

INSTRUMENT INFORMATION: MARS PATHFINDER IMP WINDSOCKS

Instrument Overview

The Imager for Mars Pathfinder (IMP) Windsock Experiment consisted of three small devices on the ASI/Met mast that changed orientation in response to wind speed and direction. IMP images show changing orientation of the windsocks compared with local vertical and the Martian surface, allowing wind velocity at three different heights to be measured.

Three IMP windsock units were mounted on the ASI/Met mast at heights of 33.1, 62.4, and 91.6 cm above the solar panel. Total mass of all three devices together, including mounting struts, was 39g. The IMP windsocks functioned like conventional terrestrial windsocks in that deflection from vertical indicates wind speed, and azimuth of deflection indicates wind direction. Each windsock consisted of a hollow aluminum cone rigidly joined to an aluminum-sheathed steel counterweight spike, which together pivoted on a small, low-friction gimbal mount. Each windsock assembly was less than 10 cm long and was mounted (flexibly) at the end of a support strut extending 10 cm from the ASI/Met mast. The final design was tested in the field and in a wind tunnel at one atmosphere, and at equivalent Martian atmospheric pressure in the ASU low-pressure wind tunnel at NASA-Ames, and found to be aerodynamically stable at all deflection angles and wind speeds. Each windsock unit was constructed of electrically conductive materials and was grounded to prevent accumulation of static charge from affecting windsock deflection. Matte finishes on the aluminum cones and counterweight sheaths produced a very bright appearance in IMP images (conductive black paint was added to the cone interiors for contrast), so that sharp contrast between bright windsock components and darker scene backgrounds helped maintain integrity of the windsock appearance in compressed images.

Wind speed u is related to windsock deflection θ by equating gravitational and aerodynamic torques acting on the windsock

$$u = \sqrt{\frac{2 R_1 M g \tan\theta}{R_2 A_d \rho}} \quad [\text{Equation 1}]$$

where R_1 = distance between pivot and center of mass, M = non-counter-balanced mass, g = acceleration of gravity, R_2 = distance between pivot and center of aerodynamic pressure, A_d = effective aerodynamic cross-section, and ρ = atmospheric density (a function of pressure, temperature, and molecular weight). Counterweight length was adjusted until R_1/R_2 was optimized for sensitivity to Martian wind speeds appropriate for investigation of aeolian processes. In practice, it is not necessary to calculate R_1 , R_2 , M , and A_d (which varies with θ) individually. Eq. [1] allows windsock performance at the same deflection θ (thus same A_d) in different atmosphere/gravity environments to be related. If the windsock is deflected θ_1 degrees under two different conditions of wind speed, atmospheric density, and gravity, then eq. [1] reduces to

$$u = C_{\theta_1} \sqrt{\frac{g}{\rho}} \quad [Equation 2]$$

This means that if u is known at θ_1 for conditions g and ρ , then u for other specified conditions of g and ρ can be immediately calculated. In the general case, once the windsock unit is calibrated for $u(\theta)$ at conditions g and ρ , then $u(\theta)$ for the same deflections can be predicted for other specified conditions of g and ρ . This relationship was exploited for calibration and derivation of wind speed on the Martian surface.

Science Objectives

The IMP windsock experiment measured wind speed as a function of height close to the surface, where wind energy is transferred to potentially mobile materials such as sand and dust. This capability allowed direct measurement of the wind speed profile on the Martian surface for the first time. The objective of this experiment was to use this capability to analyze aeolian processes at the Pathfinder landing site. Scientific goals included: (1) determination of z_0 (aerodynamic roughness) for the landing site and values of u_* (wind friction speed); (2) monitoring potentially mobile materials (e.g. drifts, rover tracks, airbag scars) in coordination with real-time windsock boundary-layer analysis; (3) relating changes observed at the landing site to z_0 and values of u_* .

Science Background

The importance of aeolian activity on the surface of Mars has been well established by telescopic observation, analysis of spacecraft imagery, and experimental work. Variability of Martian surface features has been recorded telescopically since the nineteenth century, although it was not fully appreciated until the advent of spacecraft exploration that variability of the planet's surface markings was due primarily to wind-related changes [MCLAUGHLIN1954; KUIPER1957; SAGAN&POLLACK1969]. Regional dust storms can occur in many locations any time during the Martian year, while global, planet-encircling dust storms originate only during southern spring and summer [MARTIN&ZUREK1993]. A planet-encircling dust storm occurs about once every three Martian years, with significant interannual variation [HABERLE1986; ZUREK&MARTIN1993]. Such a storm was in progress when Mariner 9 arrived at Mars in 1971. As the storm abated, surface features were observed that obviously derived from wind interactions with the surface, including time-variable bright and dark streaks associated with topographic obstructions, and dune fields [e.g., SAGANETAL1972; MCCUALEY1973]. Changes in variable feature characteristics during the period spanning the Mariner 6, 7, 9, and Viking missions indicate that albedo variations on Mars are due solely to aeolian effects (and sublimation/deposition of volatiles at the poles) [e.g., EVERKAETAL1974; EVERKAETAL1977]. Viking Orbiter images revealed four major regions of dunes surrounding the north pole [CUTTSETAL1976; BREEDETAL1979; TSOARETAL1979; THOMAS1981; LANCASTER&GRIELEY1990]. Smaller deposits of dune-forming materials are common in high resolution Viking images, especially within craters and other topographic traps [e.g., BREEDETAL1979; THOMAS1981; THOMAS1984]. Barchan, star, transverse, and longitudinal dunes have been observed and their morphologies and orientations used to interpret regional wind patterns [e.g., TSOARETAL1979; BREEDETAL1979;

WARD&DOYLE1983; EDGETT&BLUMBERG1994; THOMAS&GIERASCH1995; LEE&THOMAS1995]. It is not clear whether any of these dune forms are currently active. Dune particles are presumably sand-sized [EDGETT&CHRISTENSEN1991] but their composition has not been determined. Wind tunnel experiments indicate improbably strong winds are required for direct entrainment of dust-sized particles under Martian conditions [GEELEYETAL1980; GEELEY&IVERSEN1985], so the mechanism for raising massive quantities of dust during regional and global dust storms must be complex, perhaps involving saltation and traction of larger, more easily moved particles as a triggering mechanism, desorption of volatiles within a dusty surface layer, dust devils, and/or a thermally unstable boundary layer (reviewed by [GEELEYETAL1992B]).

Accumulations of fine particles deposited and shaped by wind were observed at both Viking Lander sites [BINDERETAL1977; MUTCHEITAL1977; SHARP&MALIN1984]. Orientations of drifts correlate reasonably well with highest wind speed directions inferred from wind streaks seen from orbit [SAGANETAL1977]. However, changes to the landing sites during the mission were minor. At the MMS (Mutch Memorial Station, or Viking Lander 1 site) winds perhaps as high as 50 m/sec affected small artificial piles of soil and trenches, but did not perceptibly erode previously undisturbed materials; no wind-related morphological changes at all were observed at the Lander 2 site [ARVIDSONETAL1983; MOORE1985]. Two small mass-movements within drift material were recognized at the MMS [JONESETAL1979; GUINNESSETAL1982], suggesting that inactive drift material is not completely cemented *in situ*. One of these mass-movements was modified subsequently during the sol 1742 dust storm [MOORE1986]. Dust deposition and subsequent removal of dust by light winds occurred at both landing sites [GUINNESSETAL1982; ARVIDSONETAL1983]. The Viking Meteorology Experiment measured temperatures and wind speeds from a single location 1.6 m above the surface [HESSETAL1977; RYANETAL1978]. Modeling of heat and momentum fluxes within the near-surface boundary-layer was complicated by unknown aerodynamic roughness, z_0 , [SUTTONETAL1978; HABERLEETAL1993B; TILLMANETAL1994], a limitation of meteorology data being available from only a single height. Under these circumstances values of wind friction speed, u_* , were estimated using a range of assumed values of z_0 . The Pathfinder IMP windsock experiment, with three anemometers, has the potential to remove this ambiguity, providing an independent determination of u_* directly from the wind speed profile and allowing more constrained modeling of the atmospheric boundary layer than previously.

Aerodynamic Calibration

The three flight unit windsocks were calibrated at one atmosphere and at equivalent Martian atmosphere in the Arizona State University planetary geology wind-tunnel at NASA-Ames Research Center. Besides determining the function relating deflection of each windsock to wind speed, the variation of this function with strut azimuth (e.g., the effect of direct wind “shadowing” of the windsocks by the ASI/Met mast) was measured.

An initial test investigated the effect of dust accumulation on calibration stability. A windsock was first calibrated at one atmosphere pressure at speeds causing deflections from 5 to 85 deg, then was subjected to thick, heavy blowing dust for one hour. The windsock was coated with a patina of dust at the end of the run, but subsequent recalibration showed no change in performance.

A turntable was used for examining the behavior of each windsock at a range of strut azimuths from the mast relative to the wind direction. The adopted convention is that strut azimuth of 0 deg extends the windsock strut ahead of the mast, into the wind; 180 deg azimuth extends the windsock strut directly downwind of the mast, placing the windsock in the mast wake. Strut azimuth relative to the wind increases clockwise when viewed from overhead. During experiments at one atmosphere pressure each flight unit was photographed simultaneously from horizontal and vertical directions at seven strut azimuths and seventeen wind speeds, and at five more strut azimuths at seven wind speeds. Similar experiments were performed at Martian equivalent atmospheric pressure for seven strut azimuths at an average of eleven wind speeds. About 3000 photographs were obtained as part of the calibration process for the three flight units. None of the 1500 vertical (from overhead) pictures revealed any tendency for the windsocks to yaw away from the center of the wind tunnel slip stream. Processed negatives for each of the 1500 horizontal (from the side) photographs were projected to allow measurement of windsock deflection for each wind tunnel speed. Some minor hysteresis (1-2 degrees of deflection at the lowest wind speeds) was encountered during early experiments, so all data were obtained at both incrementally increasing and decreasing wind speeds. A “dead zone” deflection (neutral, no wind) of 5-6 degrees is typical for all three windsocks at all azimuths. Equations (1-2) relate performance between terrestrial calibrations at different conditions, and between all terrestrial calibrations and Martian conditions. Predictions for Martian conditions from terrestrial one-atmosphere and low-pressure experiments plot similarly along the same curve for each flight windsock. Windsock sensitivities for Martian atmosphere and gravity were from 5-40 m/sec. This speed range was most relevant for studying winds strong enough to move loose particles potentially affected by wind. This speed range was also complementary to the single ASI/Met wind sensor, which was optimized for precision measurement of winds <5 m/sec. The most sensitive windsock is unit #1, located at the bottom position of the array, 0.331 cm above the solar panel. Flight windsock #2 was mounted in the middle position, 0.624 m above the solar panel. The least sensitive unit, flight windsock #3, was mounted in the top position at 0.916 m above the solar panel.

Calibration data are in Appendix I. None of the images from the vertical (downward-looking) camera are included, as inspection of these images showed no yaw from the wind tunnel centerline. Horizontal (side-looking) pictures are listed by film roll number. Information for each exposure includes windsock flight unit number, date and time of exposure, strut azimuth into wind, temperature, and pressure. If the calibration image was obtained at one atmosphere, wind tunnel fan speed in Hz is listed along with the corresponding laser-doppler velocimeter wind speed at the time of exposure. If the calibration image was obtained at Martian-equivalent pressure, only the wind speed from the laser-doppler velocimeter is listed. Windsock deflection from vertical was measured from every image in at least one trial, and these deflections are also included in Appendix I. It is not practical for the PDS to distribute the original processed film negatives, but they can be examined for additional measurements, if required, by contacting Dr. Robert Sullivan, CRSR, Cornell University, Ithaca, NY 14853 (5/99).

During calibration of the flight model IMP, over 650 IMP windsock images were obtained in a matrix of 36 strut azimuths (0 to 180 deg in 5 deg increments) and 18 deflection angles. A matrix of IMP windsock images with varied lighting and background scene entropies was also obtained in order to evaluate practical image compression limits. These auxiliary calibration data showing windsocks at known

orientations allow visual comparisons with flight image data obtained on Mars, although this is not necessary for data reduction. As of this writing (5/99) it is uncertain whether these and other preflight IMP calibration images will be included in the IMP PDS distribution.

Operational Considerations

Four IMP sequences were dedicated to imaging the windsocks during mission operations: S0068, S0173, S0174, and S0175.

- (1) **S0068** This sequence was designed for use with the IMP in its stowed position, after deployment of the ASI/Met mast. A great deal of IMP contingency data were obtained before the IMP was deployed to its full height, including a single activation of S0068 for imaging the windsock array. S0068 involved 20 images that covered all three windsocks. IMP pointing uncertainties were larger than expected, resulting in partial clipping of the windsocks. Wind-related motion of the windsocks was detected, confirming their proper deployment with the ASI/Met mast.
- (2) **S0173** This 12-image sequence covered the entire windsock array. This was the main sequence for collecting wind speed profile data once IMP was deployed to its full height. The sequence was modified several times early in the mission to optimize compression ratio and adjust image cut-out window size to compensate for unexpected IMP pointing irregularities.
- (3) **S0174** This 3-image sequence was designed for use with the IMP in the stowed position, after deployment of the ASI/Met mast. The sequence involved looking only at the top windsock, to sample wind speed and direction without gathering wind profile data. The sequence was activated only once before IMP was deployed.
- (4) **S0175** This 6-image sequence was designed to look only at the top windsock, to sample wind speed and direction without gathering wind profile data. The sequence was modified several times early in the mission to optimize compression ratio and adjust image cut-out window size to compensate for unexpected IMP pointing irregularities.

All windsock imaging sequences involved rapid, repetitive imaging within a single sequence activation. Repetitive imaging of the windsocks over a short time period is necessary for averaging short-term fluctuations in wind speed and direction to obtain more meaningful wind profile data. One or more windsocks appear by happenstance in other images not intended for windsock analysis (sequences S0050, S0053, S0055, and S0166), but without rapidly repetitive coverage such images are not very useful for windsock analysis.

Windsock images in sequences S0068, S0173, S0174, and S0175 were compressed and tightly subframed to conserve downlink. However, the quality of early images from these sequences was adversely affected by (1) unexplained/unexpected poor performance of the onboard square-root compressor (which converted 12-bit image data to 8-bit data); and (2) unexpected IMP pointing irregularities which led to clipping of the subframed windsocks. These problems were overcome by using only the onboard JPEG image compressor, and increasing the size of the subframe image areas containing the windsocks.

Rover and IMP images show that substantial portions of the airbags were not completely drawn under the ASI/Met mast solar panel. It is likely that unretracted airbag bulk caused aerodynamic interference with the bottom windsock from several wind directions.

All IMP images from all windsock sequences (S0068, S0173, S0174, and S0175) are listed in Appendix II. Images containing windsocks from sequences S0050, S0053, S0055, and S0166 are also listed. Appendix II includes spacecraft clock time, SCLK, and local time of day (LST) for each image.

Measured Parameters

The primary data for windsock analysis are IMP images of the windsocks. Description and specifications of the IMP, performance of the IMP during mission operations, and characteristics of IMP image data are discussed elsewhere in the Mars Pathfinder PDS distribution.

Recommended Procedure for Deriving Wind Speed and Direction

IMP orientation relative to local Martian vertical can be calculated from IMP elevation angle and the overall lander tilt obtained during the mission from onboard accelerometers. This makes windsock deflection θ from true local vertical and azimuth ϕ completely determinable by geometrically transforming two measurements in IMP images: (1) apparent foreshortening of the windsock; and (2) clock angle of the windsock in the plane of the image. Windsock deflection from vertical can then be converted to wind speed u with equation [1] (using simultaneous ASI/Met temperature and pressure measurements to calculate density ρ) and relevant wind tunnel calibration data. Here is a recommended sequence of steps for obtaining wind speed and azimuth information from IMP windsock images:

- (1) **Obtain IMP windsock images.** Consult Appendix II to identify and select windsock images from the IMP PDS distribution. Appendix II lists all windsock images obtained by activating sequences S0050, S0053, S0055, S0068, S0166, S0173, S0174, and S0175, with corresponding LST (local solar time) for each image. Use sequences S0068 (IMP stowed) and S0173 (IMP deployed) to obtain wind profile data using all three windsocks. Use sequences S0174 and S0175 to obtain additional wind speed data from the top windsock only. Other sequences captured the windsocks incidental to other purposes, but without rapidly repetitive imaging.
- (2) **Measure the clock angle and foreshortening angle of each windsock.** The clock angle is the apparent orientation of the windsock in the image plane compared with the image frame boundaries. The foreshortening angle of the windsock is how much the windsock is pointing into or out of the image plane. The foreshortening angle of the windsock can be obtained by measuring the ratio between the apparent width of the cone base, which is independent of orientation, and a windsock length dimension. This apparent ratio is then compared with the true ratio of these physical dimensions of the windsock. It is recommended that apparent ellipticity of the cone base be used for this purpose. This dimension is easier to discern in images than any involving the exact location of the counterweight tip, which generally is obscured by bright reflections that introduce more ambiguity. Consult

Windsock.tif in this PDS distribution for detailed information on physical dimensions of a windsock. Counterweight length varied slightly among the flight units (for sensitivity tuning) compared with the dimension shown in Windsock.tif, but averaged 0.034 m.

- (3) **Transform the measured clock and foreshortening angles from (1-2) to ground azimuth and deflection-from-vertical angles.** Trigonometric conversion can be implemented in several ways, depending on the needs of the end-user, who will probably want to automate this task suited to his/her own research objectives. At the time of this writing (5/99), these are the values best known to the author for spacecraft dimensions and orientations: (a) azimuth of maximum downward tilt of the spacecraft = 52.8 deg clockwise from north; (b) magnitude of the maximum downward spacecraft tilt = 4.01 deg; (c) azimuth from the IMP to the windsocks, clockwise from north = 126.142 deg; (d) azimuth along the windsock struts from the mast to the windsock gimbal joints = 36 deg clockwise from north (about 90 deg counterclockwise from the IMP-to-mast azimuth); (e) downward viewing elevation angle of top windsock from IMP = 7.3 deg; (f) distance between IMP and top windsock = 1.98 m; (g) downward viewing elevation angle of middle windsock from IMP = 16.4 deg; (h) distance between IMP and middle windsock = 2.04 m; (i) downward viewing elevation angle of bottom windsock from IMP = 23.3 deg; (j) distance between IMP and bottom windsock = 2.106 m. These values may be updated elsewhere as part of a subsequent PDS release.
- (4) **Determine atmospheric density when the windsock image was obtained.** Obtain ASI/Met temperature and pressure data from the PDS that are as nearly simultaneous as possible with the windsock image. Use the windsock image SCLK and LST values provided in Appendix II to locate the most appropriate temperature and pressure values from ASI/Met data. The LST values listed with ASI/Met data are only approximate, so use the SCLK values of IMP windsock images and ASI/Met data to locate periods of simultaneity between these data. Calculate the atmospheric density, ρ , using the relevant ASI/Met temperature and pressure data.
- (5) **Determine the strut azimuth into the wind.** This information will be used for locating relevant calibration data. The strut azimuth into the wind is obtained by comparing the windsock azimuth clockwise from north found in step (3) with the azimuth of the windsock strut (36 deg east of north, as specified in step 3).
- (6) **Obtain relevant calibration data.** Access the appropriate calibration chart, WS1calib.tif, WS2calib.tif, or WS3calib.tif included in this PDS distribution for windsock 1, 2, or 3, respectively. Each chart shows what calibration data are available at twelve strut azimuths, at both one atmosphere and at Martian equivalent pressure. Locate the azimuth segment from (5) on the calibration chart, and to determine what calibration data are available and the film roll it is located on. The actual calibration data, including deflection, temperature, and pressure, are listed by film roll number in Appendix I. Deflection values in Appendix I include measurements made during both ascending and descending wind speeds; averaging of these deflections at each wind speed, where possible, is recommended.
- (7) **Calculate wind speed.** Calculate wind speed, u , from the results of (3-6) and appropriate calibration data from (5-6), using equations [1-2] to relate parameters between Martian and (terrestrial) calibration environments that share the same deflection angle θ . More calibration data were obtained at one atmosphere than at low pressure, so it is recommended that the one-atmosphere data be

used for interpreting Martian data using equations [1-2]. This is especially so considering that there are more one-atmosphere calibration data at the smallest deflections, which were typical during the quiescent wind conditions at the landing site during Pathfinder mission operations.

Additional Sources of Information

Inquiries for additional information about the Pathfinder IMP windsock experiment, windsock data in this PDS distribution, or the content of this document (apart from questions regarding PDS distribution generally) should be directed to Dr. Robert Sullivan, CRSR, Cornell University, Ithaca, NY 14853 (5/99).

APPENDIX I. IMP WINDSOCK CALIBRATION DATA

Film Roll: The number of the roll of film on which the windsock image appears. There were eight rolls of film.

Flight Windsock: Flight windsock unit 1, 2, or 3.

Strut Azimuth: Strut azimuth of 0 deg extends the windsock strut ahead of the mast, into the wind; 180 deg azimuth extends the windsock strut directly downwind of the mast, placing the windsock in the mast wake. Strut azimuth increases clockwise when viewed from overhead.

Exp. Date: Date of exposure of windsock picture.

Exp. Hour: Hour of exposure of windsock picture.

Exp. Min: Minute of exposure of windsock picture.

AM/PM: Morning or afternoon specification of exposure of windsock picture.

Temp (K): Approximate temperature of the atmosphere in degrees Kelvin.

Press (mb): Atmospheric pressure in milibars. Pressures for one-atmosphere exposures are approximated as 1015 mb.

Fan Speed (Hz): For one-atmosphere exposures only, the speed setting of the wind tunnel fan.

Wind Speed (m/s): Wind speed in meters/second recorded by the laser-doppler velocimeter.

Defl Angle (deg): Deflection angle of the windsock from vertical measured from the picture. The letter "B" associated with a measurement means that the windsock was partly blocked in the picture by the mast or other apparatus.

Defl Angle (trial 2) (deg): A second trial measurement, from the original film, of deflection of the windsock from vertical.

Defl Angle (trial 3) (deg): A third trial measurement, from the original film, of deflection of the windsock from vertical.

Defl Angle (trial 4) (deg): A fourth trial measurement, from the original film, of deflection of the windsock from vertical.

| Film Roll | Flight Wind-sock | Strut Azimuth (deg) | Exp. Date | Exp. Hour | Exp. Min | AM/ PM | Temp (K) | Press (mb) | Fan Speed (Hz) | Wind Speed (m/s) | Defl. Angle (deg) | Defl. Angle (trial 2) (deg) | Defl. Angle (trial 3) (deg) | Defl. Angle (trial 4) (deg) |
