

Data Providers' Handbook
Archiving Guide to the PDS4 Data
Standards

DRAFT

Data Design Working Group
1 October 2012
Version 0.3.9

CHANGE LOG

Revision	Date	Description	Author
0.1	Mar 30, 2009	Initial draft based on information collected by the Data System Working Group.	R.Joyner
0.2	Aug 6, 2009	Updated versions of all Classes	R. Joyner
0.2.1	2010-08-31	Complete overhaul, but only partly successful through page 25	R. Simpson
0.22	Aug 31, 2010	Integrate Simpson and Joyner docs	R. Joyner etal
0.22.1	2010-09-22	Edits through Section 3, except Section 2	Simpson
0.22.2	2010-09-24	Added comments from Mitch Gordon	Simpson
0.22.2	2010-10-01	Significant edits to Section 4	Simpson
0.22.3	2010-10-25	Significant edits to Sections 1,3-6	Simpson
0.3	2011-04-15	Significant edits addressing Build 1b comments	M.Gordon etal
0.3.1	2011-04-21	Additional content added	M.Gordon etal
0.3.2	2011-05-02	Significant reorganization, additional edits	M.Gordon etal
0.3.3	2011-06-29	Make Sections 1-2 more user friendly	R. Simpson, M. Gordon
0.3.4	2011-09-06	Major changes Sections 2, 3, 8,14	M. Gordon, R. Joyner
0.3.5	2011-10-31	Updates for schema 0.5.00g	M. Gordon, R. Joyner
0.3.6	2012-01-31	Updates for schema 0.7.0.0.j	M. Gordon, R. Joyner
0.3.7	2012-03-28	Updates for schema 0.7.0.0.j	M. Gordon, R. Joyner
0.3.8	2012-05-28	Updates for schema 0.8.0.0.k	M. Gordon, R. Joyner
0.3.9	2012-10-01	Updates for schema 0.3.0.0a	M. Gordon, R. Joyner

1.0 INTRODUCTION

Planetary Data System version 4 (PDS4) represents a departure from previous versions of the PDS. Although it is still an archive of planetary data, it has been designed using contemporary information technology concepts and tools. The system is built around a ‘data model’ that rigorously defines each of its components and the relationships among them. There are only four fundamental data structures, but many extensions are possible — each also rigorously defined. By carefully controlling product definitions and relationships, PDS can accurately track the progress of each product entering the system, compute detailed inventories of holdings, design sophisticated services that users can request to act on subsets of the archive (such as transformations and displays, in addition to the expected search and retrieval functions), and connect data products to relevant internal and external information (documentation).

Note that this version of the document is conformant to version “0.3.0.0.a” of the Information Model.

1.1 Purpose

The *Data Providers Handbook (DPH)* is a guide for preparation of data being submitted to PDS4. It will walk you through preparation of very simple products, collections of products, and bundles of collections, which are the units in which deliveries are made to PDS4.

1.2 Audience

The *DPH* is written for scientists and engineers in the planetary science community who are planning to submit new or restored data to PDS4 (data providers). While the document is applicable to all such submissions, most of the examples and discussions are presented in a mission/instrument context.

1.3 Reader Preparation

The *DPH* is one of several documents describing the PDS4 system.

Readers, even those very familiar with previous versions of PDS, **should read the *PDS4 Data Standards Concepts Document* [4] and the *Glossary of PDS4 Terms* [5] before beginning the *Data Provider’s Handbook*.**

The *DPH* should be used in conjunction with the *PDS Standards Reference* (PDSSR) [2] and the *PDS4 Data Dictionary* [3a,b], which have been updated for PDS4. For more information on the individual documents, see the *Introduction to the PDS4 Document Set* [7].

1.4 XML Editors

PDS4 is implemented in the eXtensible Markup Language (XML), a set of ‘open source’ rules for encoding documents and data structures in machine-readable form with special applicability to providing web services. It is beyond the scope of the *DPH* to include an XML tutorial; however, Appendix B “Reading a PDS4 XML Schema” provides some introductory information.

The use of an XML editor simplifies construction and validation of schemata (the plural of ‘schema’) and labels. Two editors have been popular during development of PDS4.

oXygen <http://www.oxygenxml.com> which is licensed software, and
Eclipse <http://www.eclipse.org/> which is open source software.

1.5 Document Notation

A few words have meanings which differ depending on the community in which they are used. We have adopted modifiers to help distinguish among multiple uses. For example, ‘attribute’ is widely used in both PDS and XML — but its meaning in each case is different. In this document we use ‘PDS attribute’ and ‘XML attribute’ to establish the context.

PART I. PRELIMINARIES

2.0 BUILDING BLOCKS

2.1 Terminology

The results of our exploration of the Solar System can be loosely described as *data objects*; these can be electronic files, dust samples, or a sense of awe at the wonder of the universe. For purposes of archiving, we need a *description* to accompany each data object — in the case of an electronic file, a digital object, we need both the structure and meaning of the file contents for it to be useful. We can't fit dust samples or senses of awe into PDS4, but we can fit their descriptions. A description paired with its data object (when available — *e.g.*, if a digital object) is called an *information object*. If many data objects have similar characteristics, we can group them into a *class* and the common characteristics are the defining *attributes* of that class.

A *product* is one or more closely related information objects for which the descriptions have been combined into a single XML *label* and for which the product has a PDS-unique *identifier*. Closely related products may be grouped into a *collection*; in fact, every product entering PDS must be a member of some collection. Closely related collections may be grouped in a *bundle*.

For example, a planetary image, the histogram of its pixel values, and the descriptions of both could be organized as a product. Many such products — perhaps of the same target — could be defined as a collection. Image collections from many targets along with appropriate documentation, calibration, etc. (separate collections) could be a bundle, which would be a deliverable to PDS.

For more rigorous definitions of the terms introduced above, see the *Glossary of PDS4 Terms* [5].

2.2 Data

A word of caution about terminology – we have tried to avoid using differently terms that have strong PDS3 connotations. Unfortunately the English language does not provide a sufficient set of meaningful, unique, unambiguous terms to meet all of our needs. Please do not rely on the names of things – review carefully the PDS4 definitions.

Recall from the PDS4 Glossary, a “Product” is one or more closely related information objects grouped together and having a single PDS-unique identifier. In the PDS4 implementation, the descriptions for all of the objects making the product are combined into a single XML label.

Four basic structural data formats are allowed in PDS4.

1. repeating_record_structure

- Suitable for fixed length tabular data.
 - May be either binary or character, but a single object may be only one of these.
 - The records are fixed length.
 - The elements of a record (fields) are heterogeneous.
 - The formats (data type and size) of fields in the same position in each record are the same (i.e., the second field in the second record is constructed identically to the second field in the first record).
2. homogeneous_array_structure
- Suitable for images, spectra, spectral cubes, maps, etc.
 - The elements of an array are homogeneous.
 - The individual elements of any array are stored with their bytes in the order dictated by their scalar type.
 - PDS requires a specific order in which the elements of the array are stored. The order is described in the Concepts Document, Section 9.3, and the Standards Reference [2], Section 5.2.

The majority of PDS4 objects can be supported by the two previous structures. For those PDS4 objects which cannot be supported by the above, we have two additional structures distinguished by whether or not software must be used to decode the information before it can be accessed for reading, display, or analysis.

3. parsable_structure
- Suitable for plain text, HTML, XML, tabular data with variable length fields and records (delimited text).
 - The contents are a byte stream which can be parsed with standard rules (e.g., comma separated entries, standard punctuation); no decoding software (e.g., Adobe Acrobat©) is required.
4. encoded_structure
- Suitable for documents, browse products, etc., but generally not for observational products.
 - Contents are a byte stream that must be decoded by software before use.
 - The use of encoded_byte_stream objects is restricted by PDS to a limited set of PDS approved external standards (e.g., PDF-A, JPEG, GIF).
 - Only in exceptional cases will encoded_byte_stream objects be considered appropriate for storing observational data. Prior PDS approval is required.

Each of these structural formats corresponds to one PDS4 “base class” and each PDS4 “base class” uses one and only one of the structural formats.

Structural Format		Base Class
• repeating_record_structure	↔	Table_Base
• homogeneous_array_structure	↔	Array

- parsable_structure ↔ Parsable_Byte_Stream
- encoded_structure ↔ Encoded_Byte_Stream

Here are a few rules (for a full description, see the Standards Reference [2], Section 5):

- Each digital object must be stored in one of the four basic data formats.
- A digital object must be contained in a single file (i.e., a digital object cannot span multiple files)
- A file may contain multiple digital objects from the same product.
- Digital objects within a file are not required to use the same storage structure.
 - Can have a header (parsable structure) and an image (array structure) in the same file.
- When multiple digital objects are contained in a file, they must be stored sequentially (i.e., readout of the file should be sequential where one object is followed by the next, not two objects interleaved).

These data structures only tell you how to read the bytes from a file; they contain absolutely no interpretation beyond that. PDS4 defines a set of base object classes that apply the first level of interpretation to the bytes read (the "It's an image" interpretation), and subclass extensions of those base object classes to expand and restrict the associated metadata for specific object types.

2.2.1 Sample Data

This document frequently references a set of example PDS4 products – see Section 14 - Example PDS4 Products.

There are two different sets of examples:

- The first is a set of example products. This includes a representative set of products that would exist within an archive (e.g., character table, binary table, document, etc.).
- The second set is an example of a complete archive. This includes all products that would comprise a complete PDS4 archive (e.g., bundle, collections, collection inventories, aareadme, errata, and basic products).

2.2.2 Methodology

To complete the sample data (from above), we created XML labels for each of the products in the archive. For simplicity, we assumed that each product is an object-description pair. The products are grouped into collections. The collections are grouped into a single “archive” bundle, and the bundle was delivered to PDS.

3.0 SCHEMA AND LABELS – AN OVERVIEW

Label development begins with an XML schema. PDS maintains a master-schema that serves as a library of generic XML schema for each product type based on the core portion of the PDS Information Model (IM).

In consultation with your PDS discipline node (DN), for each product type, determine which schema you will need. The DN will use the master-schema, possibly incorporate both discipline and mission specific schemas appropriate for the products you plan to produce, and pass a ‘tailored’ version of the schemas to you.

As the data provider, you might make minor modifications to further “tailor” the discipline and/or mission schema to produce a schema that more closely describes your data. For example, your editing might include changing some classes and attributes from ‘optional’ to ‘required’, or inserting additional discipline and possibly mission specific classes appropriate for the products you plan to produce.

Any and all changes that you might make to your tailored schema must be validated against the schema you received from the DN which, in turn, will have been validated against the master-schema on which each was based.

Finished labels must be validated against the tailored and generic schema on which they are based. Thus, in order for a label to be validated as complying with PDS4 standards, it must:

- Have correct XML syntax
- Be compliant with the class and attribute structures defined by the PDS master-schema and any relevant discipline nodes and missions in their respective XSDs
- Be compliant with the rules governing specific attributes and their values as set by the PDS schematron schemas and any relevant discipline nodes and missions in their respective schematron schemas

3.1 Pipeline Considerations

If you are developing a collection with more than a few products, you will want to automate label generation as much as possible.

There are at least two approaches:

- a) Use a schema (xsd file) as input to the pipeline software you use to generate your labels,
or
- b) Use a label template (xml file) as input to the pipeline software. One feature of many XML editors is the ability to generate such a template.

The template looks like the final label except that, depending on how you set some options, there are either no values between the XML tags, or the values which vary from one label to the next are represented by placeholders which the pipeline software will replace.

As with everything, there are advantages and disadvantages to each approach. The first consideration will probably be the software package underlying your pipeline and whether or not it is specifically designed to handle XML (e.g., the PDS supplied Label Generation Tool).

In principle, you should make as many of your edits as possible in the schema to provide yourself and PDS the most robust criteria against which to validate the individual XML label files produced for your archive.

In this handbook, we assume the pipeline will use an XML template. This provides a framework for the discussion. Even if your pipeline will use the XML schema as input, you will still need to read the sections on ‘Schema Editing’ including the section on ‘Label Template Editing’.

In this handbook, we use `Product_Table_Character` for most of our examples. The tailored schema you receive from your node may differ slightly from the ones in these examples. Our goal here is to become familiar with the contents and to understand the process.

3.1.1 Label Generation Tool

The Generate Tool provides a command-line interface for generating PDS4 Labels from either a PDS3 Label or a PDS-specific DOM object. The Generate Tool provides the ability to automatically generate values that do not map directly to the input data object (i.e. PDS3 label).

<http://pds-engineering.jpl.nasa.gov/pds2010/development/2.2.0/preparation/generate/index.html>

3.2 Permitted Schema Modifications

When you modify a schema, the resulting schema must still satisfy its parent schema’s restrictions. In principle this means you can modify the schema to make it more restrictive, and you may also add classes within certain constraints.

PDS4 master-schemas (XSD and SCH) are supplied to data providers by the PDS. Missions and other data providers may not modify these existing schemas; however, they may extend existing classes and provide their own additional attributes in their own dictionary schemas, with the approval of a PDS discipline node. The PDS4 supplied master-schema should not be modified. This schema is to be considered “read-only” and the content is immutable. If you think you have found a reason to modify this schema, contact your discipline node as something has gone terribly wrong.

The node and mission schemas are subject to modification. Your discipline node will make a best effort attempt to create ‘discipline’ and ‘mission’ schemas appropriate for the products you

plan to produce. But, as stated above, you might find that you are able to make modifications that will more closely fit the particular nature of the observational and supplementary products in the archive.

The following is a summary of the type of modifications that you, as the data provider, might find necessary to make:

- a) You may change an XML element from optional (`minOccurs="0"`) to required (`minOccurs="1"`, or some number that is less than or equal to the value specified in `maxOccurs`).
- b) You may delete an optional XML element (if `minOccurs="0"`)
- c) You may restrict the upper limit on the number of times the XML element will be used by setting `maxOccurs` to a value that is greater than or equal to the value specified in `minOccurs`, but less than or equal to the value of `maxOccurs` in the master schema.
- d) For those XML elements which have "`maxOccurs = unbounded`", you may set an explicit upper limit on the number of times the XML element will be used.
- e) If an XML element will have the same value for all products being produced from this schema you may insert that value into the XML element in the schema.
- f) During the initial tailoring, the PDS node staff may insert additional classes in either the `Mission_Area` and / or the `Discipline_Area`. The `Mission_Area` and `Discipline_Area` are classes within the `Observation_Area`.
- g) The data provider may insert additional classes in the `Mission Area` (a subsection within the `Observation_Area`).

You may not modify the `minOccurs` or `maxOccurs` attributes such that they would specify a less restrictive set of conditions. For example, if "`minOccurs = 5`" you cannot set "`minOccurs = 4`", as this would violate the initial restriction. Similarly, if "`maxOccurs = 1`", you cannot set "`maxOccurs = 2`".

There are really three options for what you will do in your schema with XML elements which are 'optional' in the parent schema:

1. The XML element will be used across all labels
2. The XML element will sometimes be used in one or more labels.
3. The XML element will not be used in any labels

There are several approaches to handling optional XML elements based at least in part on your label pipeline design. We recommend:

- Set "`minOccurs = 1`" (or some appropriate higher value) for the optional XML elements you intend to use in every label.

- Delete the optional XML elements that will not be used in any label (if “minOccurs = 0”).
- Leave “minOccurs = 0” for the optional XML elements you intend to use only for some subset of the products. When maxOccurs is unbounded, reset it to an appropriate upper value. Note maxOccurs must be greater than or equal to minOccurs.

3.3 Developing Local Data Dictionaries

Local data dictionaries (e.g., mission and discipline dictionaries) are developed by the data preparer in conjunction with discussions and review by the lead PDS discipline node. Local dictionaries contain new classes and attributes as needed to provide detailed product descriptions which cannot be defined using the existing PDS classes and attributes

A local dictionary is created when the data preparer needs to define attributes and classes specific to his mission, observing campaign, data restoration effort, etc, including but not limited to specific instrument parameters, and additional observational parameters. They are an essential tool for providing data preparer’s latitude to tailor their labels to more closely fit the particular nature of the observational and supplementary data in the archive.

A local dictionary must reside within a namespace that is unique across all other locally defined dictionaries. In order to avoid collisions among namespaces used in PDS4 labels, the namespace must either be chosen from a predefined set or created using established formation rules. Refer to the Standards Reference [2], Section 6.1 or confer with your PDS discipline node to determine and/or select an appropriate namespace for each local dictionary for your archive.

Local data dictionaries are discussed in more detail in Section 11.

PART II. THE FIRST STEPS

4.0 OUTLINE THE BUNDLE

We introduce the ‘Voyager 2 Jupiter Encounter Data’ archive that was originally produced by the PPI node and delivered to the PDS as a PDS3 dataset. This will provide the basis for all of the specific discussions which follow.

Our spacecraft is the ‘Voyager 2’ (VG2) spacecraft and the instrument is the ‘Plasma Science Experiment’ (PLS) a plasma instrument designed to detect plasma conditions throughout the Voyager trajectory.

	<i>Name</i>	<i>Abbreviation / Acronym</i>
<i>Spacecraft</i>	Voyager 2	VG2
<i>Instrument</i>	Plasma Science Experiment	PLS

4.1 Collections in the Bundle

Refer to the Standards Reference [2] and confer with your PDS discipline node to determine all of the required and appropriate collections for your bundles.

Using the archive from our sample data, the instrument team plans to submit a single “archive” bundle to PDS, for the Venus encounter data. The bundle will consist of five collections.

Bundle:

- Browse Collection
- Context Collection
- Data Collection
- Document Collection
- XML Schema Collection

4.2 Directory Organization

Our sample “archive” bundle is a fairly simple bundle that uses a fairly simple directory structure. Since there are only a small number of collections, we elect to have one directory in the bundle root for each collection.

The bundle root must contain at least one file, the XML label file for the bundle product, and may only contain one additional file – an optional readme file which if used is described in the bundle XML label file.

bundle root

```

| - bundle.xml
|
| - browse
|   | - collection_browse.xml
|   | - collection_browse_inventory.tab
|   | - collection_product1
|
| - context
|   | - collection_context.xml
|   | - collection_context_inventory.tab
|
|   | - context_product1
|   | - context_product2
|   | - context_product3
|
| - data
|   | - collection_data.xml
|   | - collection_data_inventory.tab
|   |
|   | - data_product1
|
| - document
|   | - collection_document.xml
|   | - collection_document_inventory.tab
|   |
|   | - doc_product1
|   | - doc_product2
|   | - doc_product3
|
| - schemas
|   | - collection_xml_schema.xml
|   | - collection_xml_schema_inventory.tab
|   |
|   | - xml_schema_product1

```

```
| | - xml_schema_product2
| | - xml_schema_product3
```

The root level subdirectories each correspond to a single collection. Each directory will contain the collection XML label file and the collection inventory file. Depending on the size of the collection, it may or may not contain other files.

In our example data, there is a single observational data file in the data directory, ELEMONTAB.

However, had there been multiple observational data files, it would have been reasonable for the team to decide to use the spacecraft clock count at the start of each observation as the primary reference for each observation. This would have been used as the filename root and in the Logical Identifier (LID) for each observational data product. There are several approaches to setting names for each observational product and the corresponding subdirectories.

4.3 Determine the Documentation Needed

Refer to the Standards Reference [2] and confer with your PDS discipline node to determine all of the required and appropriate documentation for your document collection(s).

You and the consulting PDS node should agree on a list of required documentation early in the design process. Documentation considered essential to understanding or using the archive and the underlying data in the archive, except for published journal articles, must be submitted as part of the archive. Journal articles may be included if permitted by the copyright holder. Each document to be archived must be prepared and saved in a PDS-compliant format. Refer to Section 11 of the Standards for a list of PDS approved formats.

In our archive example, documentation includes the following documents:

1. An errata file that describes any changes or known errors in the archive.
2. A copy of a published journal article that describes the mission (in both ASCII and HTML).
3. A copy of a published journal article that describes the instrument (in both ASCII and HTML).
4. A checksum file that lists the MD5 checksum of the files in the archive. Note that this file is not a required PDS4 document. It is included in the PDS4 archive simply because it was part of the original PDS3 data_set.

Each of the above document products is individually labeled. Both the errata and the checksum files were each labeled using the Product_File_Text schema as these documents are strictly

ASCII text. The other two document products, the mission and instrument descriptions, were each labeled using the Product_Document schema as these documents are presented in both an ASCII and an HTML version. Note that the two forms of the document, the ASCII and HTML versions, are collectively a single document product (i.e., All versions of a document are considered part of a single PDS document product).

For information on how to populate the attributes and classes in a Product_Document, consult the example PDS4 products described in Section 14 - Example PDS4 Products.

5.0 DESIGN LOGICAL AND VERSION IDENTIFIERS

Every product label contains an identifier which must be unique across all products archived with the PDS. This identifier is referred to as a LIDVID and is the concatenation of a Logical Identifier (LID) and a version identifier (VID). We'll address the construction of each in the following sections.

5.1 General Concepts

Here are some general rules:

- LIDs must be unique across PDS
- Each PDS4 LID is constructed as a Uniform Resource Name (URN)
- Each LID in a PDS archive begins with 'urn:nasa:pds'
- LIDs are case insensitive.
- LIDs are restricted to ASCII letters and numbers, dash, underscore, and period. Colons are also used but only in a very prescribed way discussed in this section.
- LID maximum length is 255 characters.

The complete set of requirements for LID construction is given in Section 7 of the PDS4 Standards Reference [2].

5.2 Constructing LIDs

Detailed requirements and formation rules are provided in the PDS Standards Reference [2], Section 7.1; we provide a brief summary here.

Recall that each basic product is delivered to PDS as a member of a collection, and that collection is a member of a bundle. LIDs are constructed based on a hierarchical set of relationships.

We can think of LIDs as constructed by concatenating fields of characters. The fields are separated by colons. This is the only use of colons permitted in LIDs.

- Bundle LIDs -- are constructed by appending a bundle specific field to 'urn:nasa:pds'.

Bundle LID = urn:nasa:pds:<bundle field>

Since all PDS bundle LIDs are constructed this way, the bundle field must be unique across all products archived with the PDS.

- Collection LIDs -- are constructed by appending a collection field to the parent bundle's LID.

Collection LID = urn:nasa:pds:<bundle field>:<collection field>

Since the collection LID is based on the bundle LID, which is unique across PDS, the only additional condition is that the collection field must be unique across the bundle.

- Basic Product LIDs -- are constructed by appending a product field to the parent collection's LID.

Product LID =
urn:nasa:pds:<bundle field>:<collection field>:<product field>

Since the product LID is based on the collection LID, which is unique across PDS, the only additional condition is that the product field must be unique across the collection.

5.2.1 Examples

The following examples are based on a hypothetical mission.

	<i>Name</i>	<i>abbreviation</i>
<i>spacecraft</i>	Super SpaceCraft 01	ssc01
<i>instrument</i>	High Resolution Photon Counter	HiResPC
<i>cruise phase</i>	Cruise, Mercury, Earth phase	Cruise

The team decides to use the spacecraft clock count at the start of each observation as the product field of the LID for observational data products.

This is all the information we need to start designing LIDs.

Cruise Phase

Bundle

 urn:nasa:pds:ssc01.HiResPC. Cruise:Data:data_derived_31234567
 urn:nasa:pds:ssc01.HiResPC. Cruise:Document:errata
 urn:nasa:pds:ssc01.HiResPC. Cruise:schema:Table_Character_0411f

5.3 VID Construction

Detailed requirements and formation rules are provided in the PDS Standards Reference [2], Section 7.2; we provide a brief summary here.

Version IDs are used for all types of products, including basic products, collections, and bundles.

- Version IDs must be of the form M.m where “M” and “m” are both integers. “M” is the “major” component of the version and “m” is the “minor” component of the version.
- The major number is initialized to one for archive products. (Zero may be used for sample products or test run products that are not intended for the archive.) The minor number is initialized to zero.

The VIDs in all of the products in our sample archive (e.g., bundle, collection, and product) are 1.0 which corresponds to the first submission for the archive (i.e., this version is the post peer-review, lien resolved version which is the first version that will be archive with the PDS and will go into the deep archive). Preliminary versions may not use version 1.0.

5.4 LIDVID Construction

Concatenate the LID and VID using a double colon as the connector. Here are sample LIDVIDs based the example LIDs in Section 5.2.1

5.4.1 Examples

Cruise Phase

Bundle

urn:nasa:pds:ssc01.HiResPC. Cruise:schema:Table_Character_0411f::1.0

5.5 LIDVIDs – The Next Step

LIDs and LIDVIDs will be ubiquitous in your archive. Be sure you have the naming convention / formation rule / algorithm correct before proceeding. When you have constructed draft LIDs and LIDVIDs contact your PDS DN to verify they are unique and conform to the requirements.

Once you and your DN have settled on a naming convention / formation rule for applying LIDs and LIDVIDs to the various products in your archive, the next step is to apply the formation rule to the pipeline that automatically generates the labels in your archive.

PART III. BASIC PRODUCT LABELS

6.0 BASIC PRODUCT LABELS - AN OVERVIEW

The labels for basic products (all products except Collection and Bundle products) structurally fall into two groups: observational products and all other basic products. We start with the former; then we will discuss the aspects of non-observational product labels which differ.

6.1 Basic Product Labels – Observational Products

6.1.1 Selecting the Appropriate Product Schema

The data provider and a representative from the DN discuss the anticipated nature of the observational data. Once the DN has sufficient information, the DN data engineer will select the appropriate schema for each product type, make modifications as appropriate to generate tailored schemas, and then pass the schemas to you, the data provider. Currently, there is a single generic “Observational” product schema from which the DN will choose from the available product types:

For binary array data:

- Array_2D
- Array_2D_Image
- Array_2D_Map
- Array_2D_Spectrum
- Array_3D
- Array_3D_Image
- Array_3D_Movie
- Array_3D_Spectrum

For binary tabular data:

- Table_Binary

For character tabular data:

- Table_Character
- Table_Delimited

For “other” data:

- Header
- Header_Encoded
- Parsable_Byte_Stream
- Stream_Text

Any basic product label may support multiple objects and multiple object types. For example, the generic Product_Observational schema can include the description of an Array_2D_Image and a Table_Character histogram of pixel values. Both object types form the single digital product.

The hook to incorporating additional allowed object types is via the File_Area_Observational class which permits the inclusion of any additional digital objects (e.g., Header, Table_Character, etc) that are specified in connection with the Array_2D_Image as a single digital product. For additional information, consult your DN.

6.1.2 Basic Product Label Organization – Observational Products

In a typical basic product label there are a set number of major blocks of information (areas). Each of these areas contains one or more classes each of which may have several attributes. The areas are:

- XML Preamble
 - Provides a declaration that the document is an XML version 1.0 document
- Root declaration
 - Provides a declaration of the root element of the XML document. The root element is based on the product type. See Section 6.1.1 for a list of the available product types.
- Identification Area
 - Provides identification information specific to the product.
- Observation Area
 - Provides classes describing the specific observation, laboratory experiment, etc.
 - Includes subsections for relevant classes specific to one or more discipline nodes, and to the mission (or equivalent name space).
- Reference List Area
 - Provides identification information for products, journal articles, etc., relevant to understanding the product. References are made to sources both internal and external to PDS.
- File Area
 - Identifies the file(s) containing the data object(s), and
 - Provides classes specific to each data object in a given file (e.g., the description and parameters of each header, table, image).

Figure 6-1 depicts the major blocks of information (areas) in a typical basic product label.

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-model
href="http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/
dph_example_products/schemas/PDS4_PDS_0300a.sch"?>

<Product_Observational xmlns="http://pds.nasa.gov/pds4/pds/v03"
xmlns:pds="http://pds.nasa.gov/pds4/pds/v03"
xmlns:phxmd="http://pds.nasa.gov/schema/pds4/phxmd/v01"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation= "http://pds.nasa.gov/schema/pds4/pds/v03
http://pds.jpl.nasa.gov/pds4/schemas/PDS4_PDS_0300a.xsd">

    <Identification_Area>        27 lines
    <Observation_Area>          76 lines
    <Reference_List>            10 lines
    <File_Area_Observational>    41 lines
</Product_Observational>
```

Figure 6-1. Example Class organization for Product_Observational

All of the basic products adhere to the structure identified in Figure 6-1. This structural consistency enables us to look at the construction of the label for a single basic product type in detail with the knowledge that the same techniques will be applicable across all label types. This structural consistency also simplifies data management and user browsing.

We will use Product_Table_Character for the following discussion.

Note that Figure 6-1 only reflects the content of the labels with respect to the major classes / areas and the underlying hierarchy within the areas. There is a significant amount of content that is not depicted including the attributes contained in the classes.

For additional information regarding the definitions and cardinality of the attributes and classes used within the definition of a basic product label, consult the PDS4 Data Dictionary. For information on how to populate the attributes and classes, consult the example PDS4 products described in Section 14 - Example PDS4 Products.

6.2 Basic Product Labels – Non-Observational Products

The Non-Observational products are still products, so the labels for non-observational products are structurally similar to those of observational products. This section highlights those differences.

6.2.1 Selecting the Appropriate Product Schema

The process for selecting the appropriate schema for the non-observational products is the same as that used for the observational products.

The data provider and a representative from the DN discuss the various types of ancillary data that will be supplied as part of the archive (e.g., documents, browse, thumbnails, etc). Once the DN has sufficient information, the DN data engineer will select the appropriate schema for each product type, make modifications as appropriate to generate tailored schemas, and then pass the schemas to you, the data provider. The DN will choose from the following possible product types:

- Product_Browse
- Product_Document
- Product_Thumbnail

Unlike observational products which can support multiple object types, non-observational product label only support a single object type. For example, the Product_Document product may only describe a single digital document product.

6.2.2 Basic Product Label Organization – Non-Observational Products

The organization of a non-observation product label is fairly well aligned to that of an observational product label. The PDS XML labels begin with a section of statements known as the XML preamble. This is followed by a section of statements that declare the root element of the PDS XML label. There is a difference in the root declaration of a non-observational product in that non-observational products will not reference local dictionaries. Therefore the preamble and root declarations only describe the references to the master-schema and the master-schematron (both of which reside within the “pds” namespace). Here is an example of these statements:

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-model
href="http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_example_products
/schemas/PDS4_PDS_0300a.sch"?>

<Product_Document xmlns="http://pds.nasa.gov/pds4/pds/v03"
xmlns:pds="http://pds.nasa.gov/pds4/pds/v03"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
http://pds.jpl.nasa.gov/repository/pds4/schemas/PDS4_PDS_0300a.xsd">
```

More information about the XML preamble and the root declaration can be found in Section 3.1 of the Standards Reference [2] or contact your discipline node. Additional information about the XML preamble and root declarations can be found on the PDS Wiki:

<https://oodt.jpl.nasa.gov/wiki/display/pdscollaboration/XML+Catalogs>

In a typical non-observational product label there are a set number of major blocks of information (areas). Each of these areas contains one or more classes each of which may have several attributes. The areas that are shared by all of the non-observational products include:

- XML Preamble
 - Provides a declaration that the document is an XML version 1.0 document
- Root declaration
 - Provides a declaration of the root element of the XML document. See Section 6.2.1 for a list of the available product types.
- Identification Area
 - Provides identification information for the product.
- Reference List Area
 - Provides identification information for products, journal articles, etc., relevant to understanding the product. References are made to sources both internal and external to PDS.

The following is a partial list of areas that are specific to one or more of the non-observational products:

- File Area_Browse
 - Identifies the file(s) containing the data object(s), and
 - Provides classes specific to each data object in a given file (e.g., the description and parameters of each browse product).
- File Area_Encoded_Image
 - Identifies the file(s) containing the thumbnail data object(s), and
 - Provides classes specific to each data object in a given file (e.g., the description and parameters of each thumbnail product).
- Document_Format_Set
 - Identifies the set of data objects that collectively form the document.
 - Provides identification information specific to each type of document format (e.g., html, pdf).
- Document_Description
 - Provides descriptive information about the document being described.

Note that the above only reflects the content of the labels with respect to the major classes / areas and the underlying hierarchy within the areas. There is a significant amount of content that is not depicted including the attributes contained in the classes.

For additional information regarding the definitions and cardinality of the attributes and classes used within the definition of a basic product label, consult the PDS4 Data Dictionary. For information on how to populate the attributes and classes of either a Document or Browse product, consult the example PDS4 products described in Section 14 - Example PDS4 Products.

6.3 Basic Product Labels – XML Declaration and Root Tag

All PDS XML labels begin with a section of statements known as the XML preamble. Here is an example of these statements:

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-model href="http://pds.nasa.gov/pds4/pds/v03/PDS4_PDS_0300a.sch"?>
```

The first statement declares the document to be an XML version 1.0 document using the UTF-8 encoding. The second statement, which spans three lines, is a declaration of how to locate the master-schematron validation file. This statement must be added. Additional discipline or node specific schematron files are referenced using similar notation.

The XML preamble is immediately followed by a section of statements that identify / declare the root element of the PDS4 XML label:

```
<Product_Observational xmlns="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:phxmd="http://pds.nasa.gov/schema/pds4/phxmd/v01"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation=" http://pds.nasa.gov/schema/pds4/pds/v03
  http://pds.jpl.nasa.gov/pds4/schemas/PDS4_PDS_0300a.xsd">
```

See Section 6.1.1 and 6.2.1 which together list of the available product types.

This section is also used to declare the ‘pds’ namespace (in which the PDS classes and attributes are defined) and additionally any other namespaces that need to be referenced for discipline and node dictionaries (in which locally defined classes and attributes are defined).

More information about the XML preamble and the root declaration can be found in Section 7.3 of this document, and in Section 3.1 of the Standards Reference [2], or contact your discipline node. Additional information about the XML preamble and root declarations can be found on the PDS Wiki:

<https://oodt.jpl.nasa.gov/wiki/display/pdscollaboration/Data+Design+Working+Group>

7.0 LABEL TEMPLATE EDITING

The XML label template, as the name implies, is an xml file that will be used as a template for generating / producing the actual XML label(s) that will be used in your archive.

We can use the tools provided in an XML aware editor to generate a label template from the master-schema (xsd). You will generate a label template for each type of product that will be used in your archive (bundle, collection, and each type of basic product).

The following is a list of the types of label templates that can exist in your archive:

- Product_Browse
- Product_Bundle
- Product_Collection
- Product_Context
- Product_Document
- Product_File_Text
- Product_Observational
- Product_SPICE_Kernel
- Product_Thumbnail
- Product_XML_Schema

7.1 Creating a Label Template

The XML label template is an xml file which looks much more like the final label than does the schema. The label template is created from the master-schema (xsd) using your favorite xml-aware editor (XAE). The steps for creating the label template are as follows:

Steps:

1. Download a copy of the current masterSchema (xsd)
2. Open the masterSchema in xml-aware editor (XAE)
3. Customize the settings
4. Create label template (xml)
5. Ensure label template is valid

For additional information on how to create a label-template can be found in Appendix E – Steps to Create a Label Template..

7.2 Label Editing

In the label-template, values which vary from one label to the next will be represented by placeholders that either you or the pipeline software will replace. In the examples in this and following sections, we show fragments of XML templates. These generally contain dummy values inserted by the XML editor, for example name1 in `<name>name1</name>`.

Values which are identical across all labels may be set to their appropriate value in the template.

In terms of making changes / editing the label template, there aren't that many types of modifications that can be made:

1. You can remove, from the label template, the classes or attributes designated as optional in the parent schema.
2. You can modify the number of times a class or attribute is repeated
3. You can set the value of an attribute to be fixed / static
4. You can specify a value from an enumerated list of values

Keep in mind that all changes / modifications to the label template must adhere to the constraints dictated by the referenced schema and schematron.

We will address each of these types of modifications in the sections that follow.

7.2.1 Label Editing - Presence / Absence of a Class or Attribute

Recall that in a schema you indicate the presence and / or absence of a class or attribute by setting the minOccurs and maxOccurs values appropriately (i.e., Setting “minOccurs=0” and “maxOccurs=0”, the XML element is not expected to be present in the label template).

You have the same control over the presence and absence of classes and attributes within the label template. Use either your favorite text editor or XML aware editor to edit the label template and simply add or delete the class or attribute from the label template. Note that using an XML aware editor allows you to validate in real time as you make your edits.

7.2.2 Label Editing – Repeating a Class or Attribute

Recall that in a schema you may indicate the number of times a class or attribute will repeat by setting the minOccurs and maxOccurs values appropriately. For example, if the schema specifies that there are 5, and always 5, fields in one row of a table (i.e., “minOccurs=5” and “maxOccurs=5”), initially the XML editor which generated the template will have given the attribute fields a dummy value (50 in this example, not 5 which you would expect), and the template will likely have only one instance of the field subclass (XML aware editors are aware, but not especially bright). You will need to change the value for the field attribute and replicate the field class such that you have the 5 instances you need.

```

<Record_Character>
  <fields>50</fields>
  <record_length unit="byte">50</record_length>
  <Field_Character>
    <name>name1</name>
    <field_number>1</field_number>
    <field_location unit="byte">1</field_location>
    <data_type>data_type0</data_type>
    <field_length unit="byte">50</field_length>
    <field_format>field_format0</field_format>
    <unit>unit1</unit>
    <scaling_factor>0</scaling_factor>
    <value_offset>0</value_offset>
    <description>description11</description>
  </Field_Character>
  .
  . <add 3 more instances here>
  .
  <Field_Character>
    <name>name5</name>
    <field_number>5</field_number>
    <field_location unit="byte">2550</field_location>
    <data_type>data_type0</data_type>
    <field_length unit="byte">50</field_length>
    <field_format>field_format0</field_format>
    <unit>unit1</unit>
    <scaling_factor>0</scaling_factor>
    <value_offset>0</value_offset>
    <description>description11</description>
  </Field_Character>
</Record_Character>

```

Repeat classes and attributes within the label template must adhere to the restrictions specified in the reference schema.

7.2.3 Label Editing - Set the Value of an Attribute to be Fixed / Static

For attributes with fixed values, like the number of fields in a record of a fixed width table, you can insert the appropriate value directly into the template. However, in order to ensure that attribute appears in your XML label with the correct value you will also need to write a ‘rule’ in your XML Schematron file. Strong validation is the key to an accurate archive, so you almost certainly will need to create a node or discipline specific schematron file. See Appendix C for more information on how to construct “rules” that will ensure the value of an attribute is fixed / static or the value conforms to an enumerated list of values. An example of a schematron “rule” follows:

```

<sch:pattern>
  <sch:rule context="pds:Identification_Area">
    <!-- ===== -->
    <!-- Test: ensure 'information_model_version' value -->
    <!-- matches expected-value -->
    <!-- ===== -->
  </sch:rule>
</sch:pattern>

```

```

<sch:assert test="pds:information_model_version='0.3.0.0.a'">
  Identification_Area.information_model_version: does NOT specify
  the current version.
</sch:assert>
</sch:rule>
</sch:pattern>

```

The above rule ensures that the `information_model_version` is fixed to a value of ‘0.3.0.0.a’.

```

<Identification_Area>
  <logical_identifier>
    urn:nasa:pds:sampleProducts:Array2D_Image.MEX-V1.0
  </logical_identifier>
  <version_id>1.0</version_id>
  <title>MARS
    PATHFINDER LANDER Experiment</title>
  <information_model_version>0.3.0.0.a</information_model_version>
  <product_class>Product_Observational</product_class>
</Identification_Area>

```

An example of a schematron rule that ensures the value of an attribute matches a value from an enumerated list of values follows:

```

<sch:pattern>
  <sch:rule context="pds:Array">
    <sch:assert test="pds:encoding_type = ('Binary', 'Character')">
      The attribute pds:encoding_type must be equal to one of the following
      values 'Binary', 'Character'.</sch:assert>
    </sch:rule>
  </sch:pattern>

```

For additional information regarding the use of schematron schemas and the construction of schematron rules, see Appendix C or consult your discipline node.

For examples, consult the example PDS4 products described in Section 14 - Example PDS4 Products.

7.3 XML Declaration – Preamble and Root Tag

This section addresses how the XML preamble and root tag of an XML document is created.

```
<?xml version="1.0" encoding="UTF-8"?>
```

```
<?xml-model
href="http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_exam
ple_products/schemas/PDS4_PDS_0300a.sch"?>

<Product_Collection xmlns="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
file:/D:/schemas/PDS4_PDS_0300a.xsd">
```

7.3.1 XML Preamble – XML Declaration

The first line declares the document to be an XML version 1.0 document using the UTF-8 encoding. The XML declaration must be the first line and is static. When you create your label template, the XML declaration is auto-populated by the XML-aware editor.

```
<?xml version="1.0" encoding="UTF-8">
```

Information about this line can be found at:

<http://www.w3.org/TR/REC-xml/#sec-rmd>

The second line is a declaration of how to locate the master-schematron validation file.

```
<?xml-model
href="http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_exam
ple_products/schemas/PDS4_PDS_0300a.sch"?>
```

Additional discipline or node specific schematron files are referenced using similar notation.

```
<?xml-model
href="http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_exam
ple_products/schemas/PDS4_PDS_0300a.sch"?>
<?xml-model
href="http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_exam
ple_products/schemas/PDS4_IMG_Camera.sch"?>
```

7.3.2 XML Root Element Declaration – Product Type

The XML preamble is immediately followed by a section of statements that identify / declare the root element of the PDS4 XML label – the root element declaration:

```
<Product_Observational xmlns="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:phxmd="http://pds.nasa.gov/schema/pds4/phxmd/v01"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
http://pds.jpl.nasa.gov/pds4/schemas/PDS4_PDS_0300a.xsd">
```

See Section 6.1.1 for a list of the available product types.

This section is also used to declare the ‘pds’ namespace (in which the PDS classes and attributes are defined) and additionally any other namespaces that need to be referenced for discipline and node dictionaries (in which locally defined classes and attributes are defined).

There are two components to this line. The first leftmost component specifies one of the approved PDS product types (e.g., Product_Document, Product_Collection, etc). The second component references the URI of the component. The URI of the component is derived from the schema that references the PDS product. In our example above:

- product type: Product_Collection
- URI: xmlns="http://pds.nasa.gov/pds4/pds/v03"

Since the Product_Collection is defined in the master-schema, the URI is derived from the master-schema:

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- PDS4 XML/Schema for PDS4_0.3.0.0.a Fri Sep 14 18:01:16 PDT 2012 -->
<!-- Generated from the PDS4 Information Model V0.3.0.0.a -->
<!-- *** This PDS4 product schema is a preliminary deliverable. *** -->
<!-- *** It is being made available for review and testing. *** -->
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns="http://pds.nasa.gov/pds4/pds/v03"
  targetNamespace="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v03"
  elementFormDefault="qualified"
  attributeFormDefault="unqualified"
  version="0.3.0.0">
```

Notice in the above snippet that the “xmlns:pds” namespace is defined as a URI:

```
xmlns:pds="http://pds.nasa.gov/pds4/pds/v03"
```

This URI is carried over to the XML root element declaration of our example Product_Collection XML document.

```
<Product_Collection xmlns="http://pds.nasa.gov/pds4/pds/v03"
```

7.3.3 XML Root Element Declaration – Schema Instance

The next statement in the root element declaration declares that the document conforms to the underlying schema (in the XML schema instance namespace).

```
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
```

When you create your label template, the XML declaration is auto-populated by the XML-aware editor.

7.3.4 XML Root Element Declaration – Schema Location

The next statement in the root element declaration specifies the location of the XML schema that is referenced by the XML document. Note that there are variants as to how the schema location is specified. We will address the types of specifications.

In our example, there are two components to this line. The first leftmost component is the URI of the schema referenced by the Product_Collection XML document. The second rightmost component is, in this case, the physical location / path to the schema (e.g., D:/schemas/PDS4_PDS_0300a.xsd).

```
xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
file:/D:/schemas/PDS4_PDS_0300a.xsd">
```

When you create your label template, the XML declaration is auto-populated by the XML-aware editor. Both the URI and the location / path are derived from the schema. However, you might have to change the location / path as the label template and schema progress through the development stage.

7.3.4.1 Schema Location – Physical Location

Here are alternate methods for specifying the physical location / path of the schema.

- Schema and label template are co-located:

```
xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
file:/PDS4_PDS_0300a.xsd">
```

- Schema is located in a parent directory to label template:

```
xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
file:../PDS4_PDS_0300a.xsd">
```

7.3.4.2 Schema Location – Online Accessible Location

Another method for referencing the location of the schema is through a reference to a URL that is online accessible.

- Schema is online accessible:

```
xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
http://pds.nasa.gov/schemas/PDS4_PDS_0300a.xsd">
```

7.3.4.3 Schema Location – Using XML Catalog

Yet another method for referencing the location of the schema is by using an XML catalog.

```
xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03 junk.xsd">
```

Note that “junk.xsd” is not a reference to an actual file. There is currently a “bug” in how the URI is being referenced and a file reference is required and must be specified (even though the file is not used / referenced – hence “junk.xsd” as an indicator that at some future time this will be resolved). It looks like the bug has been repaired in oXygen version 14.0. In which case the entry should be:

```
xsi:schemaLocation="http://pds.nasa.gov/pds4/pds/v03
http://pds.nasa.gov/pds4/pds/v03/PDS4_PDS_0300a.xsd"
```

For additional information on using an XML catalog to reference the schema, consult the appendix on XML Catalog Reference.

7.4 XML Root Element Declaration with Local Dictionary

This section addresses how the root element declaration section of an XML label, having a local dictionary, is created. Most of your Observational products will presumably contain references to one or more local dictionaries. Each dictionary will reside in a namespace.

Recall from our previous Product_Collection XML label snippet that the only namespace that was specified was the “pds” namespace:

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-model
href="http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_exam
ple_products/schemas/PDS4_PDS_0300a.sch"?>

<Product_Collection xmlns="http://pds.nasa.gov/pds4/pds/v03"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
file:/D:/schemas/PDS4_PDS_0300a.xsd">
```

In the case of an XML label that describes a Product_Collection product that the label will only reference the “pds” namespace. Our next example uses the Product_Observational product where the product is assumed to reference node and/or discipline specific dictionaries.

The root element declarations of XML labels, that reference local dictionaries, require each namespace to be identified. Our next example includes a reference to a single local dictionary in the “dph” namespace.

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-model
href="http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_exam
ple_products/schemas/PDS4_PDS_0300a.sch"?>
```

```
<Product_Observational xmlns="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:dph="http://pds.nasa.gov/schema/pds4/dph/v01"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
http://pds.jpl.nasa.gov/pds4/schemas/PDS4_PDS_0300a.xsd">
```

From the above example, you can see that the “dph” namespace has the following URI:

```
xmlns:dph="http://pds.nasa.gov/schema/pds4/dph/v01"
```

If you have been following the association between the schema and the referenced URI, you will not be surprised that the “dph” local dictionary specifies the URI that is to be used when referencing the “dph” schema:

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  targetNamespace="http://pds.nasa.gov/schema/pds4/dph/v01"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:dph="http://pds.nasa.gov/schema/pds4/dph/v01"
  elementFormDefault="qualified"
  attributeFormDefault="unqualified" version="0.3.0.0.a">
```

Had the XML document referenced multiple local dictionaries, you simply repeat the reference to each namespace identified by each local dictionary.

```
<?xml version="1.0" encoding="UTF-8"?>
<Product_Observational xmlns="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v03"
  xmlns:dph="http://pds.nasa.gov/schema/pds4/dph/v01"
  xmlns:phxmd="http://pds.nasa.gov/schema/pds4/phxmd/v01"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/pds/v03
http://pds.jpl.nasa.gov/pds4/schemas/PDS4_PDS_0300a.xsd">
```

In the above example, both the “dph” and the “phxmd” local dictionaries are referenced, each using a namespace that is unique to the particular node or discipline dictionary.

7.5 Next Steps

In any case, you will want to have a fully functional PDS4 compliant label template in place before proceeding onto the next step of integrating the pieces into the pipeline production of the various products in your archive.

7.6 Example XML Preambles

For additional information regarding the XML preamble and the root element declaration and how they are used within a Product Label, consult your discipline node.

For examples, consult the example PDS4 products described in Section 14 - Example PDS4 Products.

PART IV. COLLECTIONS, BUNDLES, DELIVERY PACKAGES

8.0 COLLECTIONS

The next higher level in the organizational hierarchy of an archive is the Collection — an inventory of member products and an accompanying label (including an identifier). The inventory and label are known as a Collection Product. Products of similar type and content are grouped into a collection. Observational data, for example, will be gathered into an observational data collection; documents into a document collection; and supplementary data into a supplementary collection.

In consultation with your DN, for each product type, determine how best to group the products, that share common characteristics, into appropriate collections.

To define a collection, the archivist creates a collection inventory, a specific type of character table, that lists / references the logical identifiers (LIDs or LIDVIDs) of all the product label files (XML) that are part of the collection. The archivist then creates a collection label that describes the collection inventory.

A collection label contains a logical identifier (LID) that uniquely identifies the collection and provides the links between products that share common characteristics.

The products listed in the collection inventory must be physically located either in the same directory as the collection label, or in one or more subdirectories to it.

For information on how to populate the attributes and classes in a collection, consult the example PDS4 products described in Section 14 - Example PDS4 Products.

8.1 Members of a Collection

The Members of a collection are designated as being either primary or secondary.

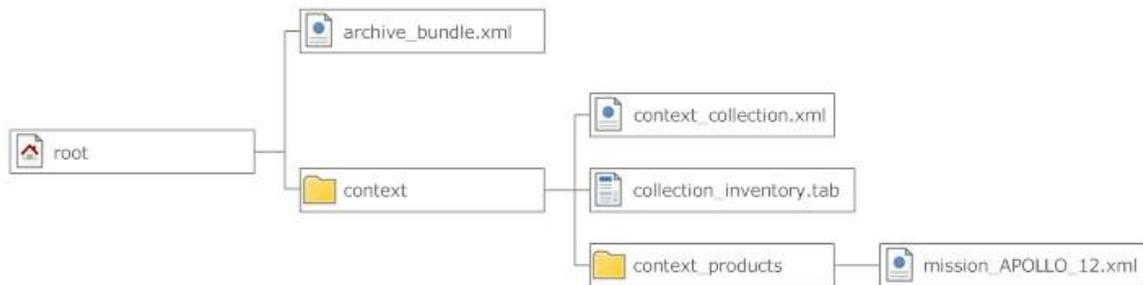

- Every product must be a primary member of one and only one collection.
 - That collection is the one in which the product is registered in the PDS repository.
- Products already registered in the PDS repository may be secondary members of other collections.
 - For example a collection of mosaic products might include the source products for each mosaic as secondary members of the collection.
- Primary members must be identified in the collection inventory using LIDVIDs.

- Secondary members may be identified in the collection inventory using either LIDs or LIDVIDs based on which is more appropriate for that collection and product.

8.2 Collection Inventory

Each collection product consists of two files, a collection XML label and a collection inventory. Depending upon the type of collection, the collection inventory, a listing of the products that are the members of the collection, is a two column character table where each row of the table describes one of the member products of the collection.

The first column of the table specifies whether the product is either a primary (P) or secondary (S) member of the collection. The second column of the inventory table specifies either the LID or LIDVID of the product.

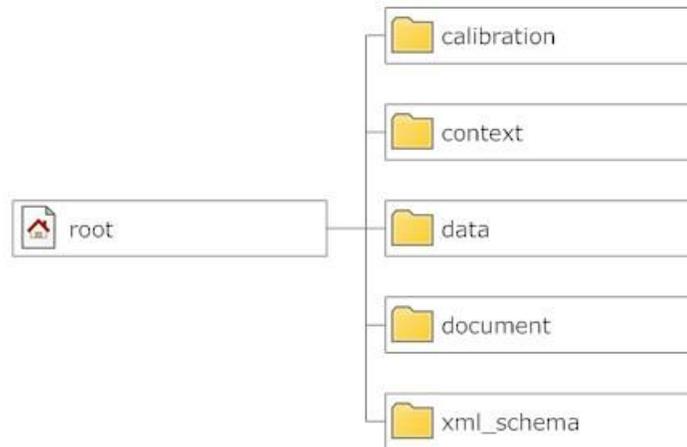

In the above diagram for the mission_APOLLO_12 context product:

1. The 1st column would be a single character which identifies the product as being either a primary (P) or secondary (S) member of the collection. In our example, the product will be considered as being a primary member of the collection.
2. The LIDVID would be the value of the <logical_idenfifer> in the mission_APOLLO_12.xml file. Recall that LIDVIDs are required for primary members.

8.3 Generating and Populating a Collection Label

Using an XML aware editor, the archivist generates a label template using the master-schema and selecting the Product_Collection class.

You will create a collection product for each collection in the archive. For example, if your archive has calibration, context, data, document, and xml_schema collections, the directory structure would be:

You would create a separate collection / inventory of the products contained in each collection, and those collection products would be located at the root level of their respective subdirectories.

8.4 Collection Product Label – Block by Block

8.4.1 Identification Area

The Identification Area block in the template looks something like this:

```

<Identification_Area>
  <logical_identifier>logical_identifier0</logical_identifier>
  <version_id>version_id0</version_id>
  <title>title0</title>
  <information_model_version>
    information_model_version0
  </information_model_version>
  <product_class>product_class0</product_class>
  <Alias_List>
    <Alias>
      <alternate_id>alternate_id0</alternate_id>
      <alternate_title>alternate_title0</alternate_title>
      <comment>comment0</comment>
    </Alias>
  </Alias_List>
  <Citation_Information>
    <author_list>author_list0</author_list>
    <editor_list>editor_list0</editor_list>
    <publication_year>publicatio</publication_year>
    <description>description0</description>
    <keyword>keywords0</keyword>
  </Citation_Information>
  <Modification_History>
    <Modification_Detail>
      <modification_date>0000</modification_date>
      <version_id>version_id1</version_id>
      <description>description1</description>
    </Modification_Detail>
  </Modification_History>
</Identification_Area>

```

```
</Modification_History>
</Identification_Area>
```

The Identification Area of the collection is identical to that of the Basic Product (i.e., there are no differences in populating the Identification_Area of either the collection or the Basic Product. See Section 3.2 in the Standards Reference [2] for additional information on populating the Identification_Area.

8.4.2 Context Area

Populating entries in the Context_Area of the collection is similar to populating the Observation_Area of the Basic Product. See Section 3.3 in the Standards Reference [2] for additional information on populating the Observation_Area / Context_Area.

8.4.3 Reference_List Area

Populating entries in the Reference_List area of the collection is identical to that of the Basic Product. See Section 3.4 in the Standards Reference [2] for additional information.

8.4.4 Collection Area

The Collection area contains a single attribute – collection_type. For each collection (e.g., calibration, context, etc), you will indicate the type of collection being described by setting the value of the collection_type attribute in the Collection class to one of the following values:

- Browse
- Calibration
- Context
- Data
- Document
- Geometry
- Miscellaneous
- SPICE
- Schema

8.4.5 File Area

The File Area of a collection product is used to reference the collection inventory (which in turn references the member products of the collection). The File_Area_Inventory class has specific purposes with respect to referencing primary and / or secondary products.

If you are still uncertain as to whether or not the products to be inventoried are primary or secondary, consult your PDS discipline node.

We are going to use the example of a collection where the collection references both primary and secondary products. If your collection only references either primary or secondary products, then tailor the following steps accordingly.

In our example, your collection will consist of two files:

- collection.xml
- collection.tab

The collection.xml XML label will reference the collection_inventory.tab file. The collection_inventory.tab will contain the inventory of both the primary and secondary products.

8.4.5.1 File Area Inventory (Primary and Secondary)

Our example has references to both primary and secondary products. We will create a single instance of the File_Area_Inventory class; one class can and will describe both the primary and the secondary members.

```
<File_Area_Inventory>
  <File>
    <file_name>collection_browse_inventory_20110823.tab</file_name>
    <local_identifier>collection_browse_inventory</local_identifier>
    <creation_date_time>2011-08-23T11:53:24.5749Z</creation_date_time>
    <file_size>513</file_size>
    <records>1</records>
    <md5_checksum>899fba057920491a08c7d517bd65e717</md5_checksum>
  </File>
  <Inventory>
    <local_identifier>dph_example_collection</local_identifier>
    <offset unit="byte">0</offset>
    <external_standard_id>PDS_DSV V1.0</external_standard_id>
    <encoding_type>Character</encoding_type>
    <records>1</records>
    <record_delimiter>carriage_return_line_feed</record_delimiter>
    <field_delimiter>comma</field_delimiter>
    .
    .
  </Inventory>
</File_Area_Inventory>
```

The File_Area_Inventory contain a File area and an Inventory area. The File Area of the collection product XML label document is used to reference the data file (i.e., the string of bits) being described by our collection label. The File area for a collection product is populated identically to that of a Basic Product. Refer to Section 3.5 in the Standards Reference [2] for additional information.

The Inventory area provides the information that describes a simple two column delimited character table where each row of the table describes one of the products in the collection. The first column is a single character which identifies the product as being either a primary (P) or secondary (S) member of the collection. The second column of the table is the LID or LIDVID or the product.

The following label snippet is an example of how a File_Area_Inventory area is populated with metadata to describe an inventory of primary products (i.e., a two column character table). The table describes 10 records / rows of data, where each row is 513 bytes; each column contains 255 characters, and each row is terminated with <CR><LF>.

```

<File_Area_Inventory>
  <File>
    <file_name>collection_browse_inventory.tab</file_name>
    <local_identifier>collection_browse_inventory</local_identifier>
    <creation_date_time>2012-08-21T11:53:24.5749Z</creation_date_time>
    <file_size unit="byte">60</file_size>
    <records>1</records>
    <md5_checksum>e594828517d4e7e40bd5b6a16c8b880e</md5_checksum>
  </File>
  <Inventory>
    <local_identifier>dph_example_collection</local_identifier>
    <offset unit="byte">0</offset>
    <external_standard_id>PDS_DSV V1.0</external_standard_id>
    <encoding_type>Character</encoding_type>
    <records>1</records>
    <record_delimiter>carriage_return_line_feed</record_delimiter>
    <field_delimiter>comma</field_delimiter>

    <Record_Delimited>
      <fields>2</fields>
      <maximum_record_length unit="byte">259</maximum_record_length>

      <Field_Delimited>
        <name>Member_Status</name>
        <field_number>1</field_number>
        <data_type>ASCII_String</data_type>
        <maximum_field_length unit="byte">1</maximum_field_length>
        <description>
          This columns specifies the LIDVID of the files that
          comprise the collection.
        </description>
      </Field_Delimited>
      <Field_Delimited>
        <name>LIDVID_LID</name>
        <field_number>2</field_number>
        <data_type>ASCII_LIDVID_LID</data_type>
        <maximum_field_length unit="byte">255</maximum_field_length>
        <description>
          This columns specifies the LIDVID of the files that
          comprise the collection.
        </description>
      </Field_Delimited>
    </Record_Delimited>

    <reference_type>inventory_has_member_product</reference_type>
  </Inventory>

```

```
</File_Area_Inventory>
```

In the above label snippet, the first column has been set to 1 character which is the maximum number of characters that this column can specify. The second column has been set to 255 characters which is the maximum number of characters that a LIDVID can have. The two columns of data are separated by a <comma> character and each record is terminated with <CR><LF> characters.

```

          1          2          250
12345678901234567890 . . . 12345678901234567
P,urn:nasa:pds:DPH:root::1.0CL
```

8.5 XML Schema Collection

Probably one of the last collections that you will create will be the XML schema collection. This collection consists of an inventory of all of the schemas that were used in creating the products in your archive.

The label for the xml_schemas collection label is virtually identical to the other collection labels.

8.6 Example Collection Product Label

For additional information regarding the definitions and cardinality of the attributes and classes used within the definition of a Collection label, or consult the PDS4 Data Dictionary. For information on how to populate the attributes and classes in a collection, consult the example PDS4 products described in Section 14 - Example PDS4 Products.

9.0 BUNDLES

The highest level product is referred to as a Bundle — an inventory of member products and an accompanying label (including an identifier). Like collections, bundles consist of a list of references to products; however in this case, the referenced products are collections. A bundle . A bundle identifies all of the collections in the archive; while the collections together identify all of the basic products in the bundle. The inventory and label are known as a Bundle Product. Unlike collection products, the bundle inventory is a table contained in the XML label file describing it, not in a separate table file.

To define a bundle, the archivist creates a Product_Bundle label. A bundle label contains a logical identifier (LID) that uniquely identifies the bundle and provides the links between the collection products in the archive.

For information on how to populate the attributes and classes in a bundle, consult the example PDS4 products described in Section 14 - Example PDS4 Products.

9.1 Generating and Populating a Bundle Label

Using an XML aware editor, the archivist generates the Product_Bundle label.

You will create a single bundle product for the archive with references to the member collections in the archive.

9.2 Identification Area

Populating entries in the Identification_Area of the bundle is identical to that of the Collection and the Basic Product. See Section 3.2 in the Standards Reference [2] for additional information on populating the Identification_Area.

9.3 Context Area

Populating entries in the Context_Area of the bundle is similar to populating the Context_Area of the Collection and to populating the Observation_Area of the Basic Product. See Section 3.3 in the Standards Reference [2] for additional information on populating the Observation_Area / Context_Area.

9.4 Reference_List Area

Populating entries in the Reference_Area of the bundle is identical to that of the Collection and the Basic Product. See Section 3.4 in the Standards Reference [2] for additional information.

9.5 Bundle Area

The Bundle area contains a two attributes – bundle_type and description. This is where you, the data provider, will want to adequately describe the bundle and indicate the type of bundle that you are producing. Since you are creating a bundle that describes an archive, you will set bundle_type to “Archive”. A non-archive bundle has a bundle_type of “Supplemental”.

```
<Bundle>
  <description>
    Some really good description of the archive goes here
  </description>
  <bundle_type>Archive</bundle_type>
</Bundle>
```

9.6 File_Area_Text

The File_Area_Text of a bundle product XML label is used to reference the ‘readme.txt’ file (i.e., the string of bits) being described by the label. This area is required if a ‘readme.txt’ is included as part of the archive.

The File_Area_Text class in the template looks something like this:

```

          <File_Area_Text>
    <File>
      <file_name>README.TXT</file_name>

    <local_identifier>document.README.TXT</local_identifier>
      <creation_date_time>2010-03-
12T11:59:04</creation_date_time>
      <file_size unit="byte">22875</file_size>

    <md5_checksum>5ef7af310b99d8189e670830c954a290</md5_checksum>
    </File>
    <Stream_Text>
      <name>readme.txt</name>

    <local_identifier>document.stream_text</local_identifier>
      <offset unit="byte">0</offset>
      <external_standard_id>TEXT</external_standard_id>
      <encoding_type>Character</encoding_type>
      <description>
        A really good description goes here.
      </description>
      <record_delimiter>
        carriage_return line_feed
      </record_delimiter>
    </Stream_Text>
```

```
</File_Area_Text>
```

Populating entries in the File_Area_Text of the XML label is remarkably straightforward. The file block consists of a number of optional and required attributes that describe the data file.

- The file name attribute, a required attribute, provides the name of the file being described.
- The local identifier attribute, an optional attribute, provides the name of the local object being described; the value must be unique within the XML label.
- The creation date time attribute, an optional attribute, provides the date/time when the file was created, either in YMD or DOY format.
- The file size attribute, an optional attribute, provides the size (in bytes) of the file.
- The records attribute, an optional attribute, provides the number of records in the file.
- The md5 checksum attribute, an optional attribute, provides the md5 checksum of the file.
- The comment attribute, an optional attribute, provides a brief description of the comment.

The next block, the Stream_Text class, contains the reference to the ‘readme.txt’ product component being described by the XML label.

```
<Stream_Text>
  <local_identifier>local_identifier1</local_identifier>
  <comment>comment1</comment>
  <encoding_type>Character</encoding_type>
  <external_standard_id>standard_id0</external_standard_id>
  <offset unit="byte">0</offset>
</Stream_Text>
```

1. As the ‘readme.txt’ file is always ASCII, the encoding type is set to ‘Character’.
2. The offset is set to indicate the starting location (in bytes) of the ‘readme.txt’ object. Populating the offset attribute for the bundle product is very simple. As there is only a single product being referenced, the offset is always set to ‘0’ bytes.

Note that the ‘readme.txt’ file referenced by the bundle product label must be co-located with the Product_Bundle product label.

Additional information on the File_Area_Text and how it is used within the archive can be found in the Standards Reference [2].

9.7 Bundle Member Entry

The Members of a bundle are referenced using the `Bundle_Member_Entry` area. The `Bundle_Member_Entry` area is repeated for each collection product reference in the bundle.

```
<Bundle_Member_Entry>
  <lid_reference>urn:nasa:pds:example.DPH.sampleArchive:browse</lid_reference>
  <member_status>Primary</member_status>
  <reference_type>bundle_has_browse_collection</reference_type>
</Bundle_Member_Entry>
<Bundle_Member_Entry>
  <lid_reference>urn:nasa:pds:example.DPH.sampleArchive:context</lid_reference>
  <member_status>Primary</member_status>
  <reference_type>bundle_has_context_collection</reference_type>
</Bundle_Member_Entry>
```

In the `Bundle_Member_Entry` class:

1. You should use / specify either the `lid_reference` or the `lidvid_reference` attribute. You normally will only specify one or the other. But, you can specify both the `lid_reference` and the `lidvid_reference` as long as both reference the identical product.
2. The value for the `reference_type` is dependent up on the type of collection being referenced:

- Browse - `bundle_has_browse_collection`
- Calibration - `bundle_has_calibration_collection`
- Context - `bundle_has_context_collection`
- Data - `bundle_has_data_collection`
- Document - `bundle_has_document_collection`
- Geometry - `bundle_has_geometry_collection`
- Miscellaneous - `bundle_has_member_collection`
- SPICE - `bundle_has_spice_kernel_collection`
- Schema - `bundle_has_schema_collection`

Note that the collection products referenced by a bundle label must reside in a subdirectory of the directory containing the bundle label.

9.8 Example Bundle Product Label

For additional information regarding the definitions and cardinality of the attributes and classes used within the definition of a Bundle label, consult the PDS4 Data Dictionary. For information on how to populate the attributes and classes in a bundle, consult the example PDS4 products described in Section 14 - Example PDS4 Products.

10.0 DELIVERIES

Transfers of products from point to point within and external to the PDS can be accomplished using a variety of mechanisms from electronic transfer by email attachment of a handful of files to the transfer of 2TB of files using external hard drives. The actual transfer mechanism should be coordinated with the node with which you are working.

Any transfer, to, from, or within PDS has three parts:

1. The required “Package” containing the material being transferred and an XML label for the “Package”
2. The “Transfer Manifest” that maps each product’s LIDVID to the file_specification_name of the product’s label file, and
3. The “Checksum Manifest” that maps the individual MD5 checksums to the materials being transferred.

10.1 The Package

Transfer packages must be approved by PDS and include options such as ZIP, gzip, tar, physical media such as thumb drives, external hard drives, etc. There is no requirement to use any of these for the transfer of a handful of files, nor is there a requirement to use software such as zip when the entire transfer is being made with a dedicated external hard drive.

The data provider and the receiving node determine the best ‘packaging’ option for the delivery.

Except for the case of the delivery of a handful of files, either as test samples or as replacements for previously delivered files, the files within the transfer package must be organized in a PDS compliant directory structure (see the PDS Standards Reference [2], Section 2 for details).

10.2 The Transfer Manifest

The “Transfer Manifest” is a file provided with each transfer to, from, or within PDS, that is external to the package. It is a manifest, for each label file in the package, that maps product LIDVIDs to file_specification_names for each product XML label file. Please note if the transfer package is a zip file, tar file, etc., the manifest must contain entries for every label file in the package once that package is unpacked. The transfer manifest is defined as a two column fixed-width table where each row of the table describes one of the products in the package. The first column defines the LIDVID of each product in the package. The second column defines the file_specification_name of each product in the package. The file_specification_name defines the name and location of the product relative to the location of the bundle product.

```

urn:nasa:pds:example.DPH.sample.browse.collection::1.0 ./browse/collection.xml
urn:nasa:pds:example.DPH.sample.browse.ELE_MOM::1.0   ./browse/ele_mom_browse.xml
urn:nasa:pds:example.DPH.sample.data.collection::1.0  ./data/collection.xml
urn:nasa:pds:example.DPH.sample.data.ELE_MOM::1.0    ./data/ele_mom_data.xml

```

Since the transfer manifest is external to the package, and hence external to the archive, there is no requirement to provide a separate PDS4 XML label. If generated as part of the transfer package, the checksum manifest is described within the XML document that describes the “package”.

The following label snippet is an example of how a File_Area_Transfer_Manifest is populated with metadata to describe a manifest of products in the package (i.e., a two column character table). The table describes 10 records / rows of data, where each row is 513 bytes; each column contains 255 characters, and each row is terminated with <CR><LF>.

```

< File_Area_Transfer_Manifest>
  <File>
    <file_name>MEX_transfer_bundle.tab</file_name>
    <local_identifier>MEX_transfer_bundle</local_identifier>
    <creation_date_time>
      2011-08-23T11:53:24.5749Z
    </creation_date_time>
    <file_size>2052</file_size>
    <records>4</records>
    <md5_checksum>899fba057920491a08c7d517bd65e717</md5_checksum>
  </File>
  <Transfer_Manifest>
    <local_identifier>mex.transfer.manifest</local_identifier>
    <offset unit="byte">0</offset>
    <records>10</records>
    <encoding_type>Character</encoding_type>
    <record_delimiter>carriage_return_line_feed</record_delimiter>
    <Record_Character>
      <fields>2</fields>
      <record_length>513</record_length>
      <Field_Character>
        <name>LIDVID</name>
        <field_number>1</field_number>
        <field_location>1</field_location>
        <data_type>ASCII_LIDVID</data_type>
        <field_length>255</field_length>
        <field_format>urn:nasa:pds:xxxx::M.n</field_format>
        <description>
          This columns specifies the LIDVID of the files that
          comprise the collection.
        </description>
      </Field_Character>
      <Field_Character>
        <name>file_specification_name</name>
        <field_number>2</field_number>
        <field_location>257</field_location>
        <data_type>ASCII_File_Specification_Name</data_type>
        <field_length>255</field_length>
        <description>
          This columns specifies the location of the files that
          comprise the collection where the location is specified

```

```

        relative to the location of the collection.
    </description>
  </Field_Character>
</Record_Character>
</Transfer_Manifest>
</File_Area_Transfer_Manifest>

```

10.3 The Checksum Manifest

The “Checksum Manifest” is a file provided with each transfer to, from, or within PDS that is external to the package. It is a checksum manifest for each file in the package. Please note if the transfer package is a zip file, tar file, etc., the manifest must contain entries for every file in the package once that package is unpacked. Currently PDS uses MD5 checksums, so the checksum manifest is just an MD5 checksum table that consists of two columns of data that is compatible with the output from an MD5 checksum utility.

```

4a9a9081a3561e54c12b7e1f6ad4c194 md5deep-3.0\CHANGES.TXT

770b6eb6911ca29c83ee2b17e3866fa0 md5deep-3.0\whirlpooldeep.exe

```

Since the checksum manifest is external to the package, and hence external to the archive, there is no requirement to provide a separate PDS4 XML label. If generated as part of the transfer package, the checksum manifest is described within the XML document that describes the “package”.

The following label snippet is an example of how a File_Area_Checksum_Manifest is populated with metadata to describe a manifest of products in the package (i.e., a simple character table). The table describes 10 records / rows of data, where each row is terminated with <CR><LF>.

```

<File_Area_Checksum_Manifest>
  <File>
    <file_name>MEX_checksum_manifest.tab0</file_name>
    <local_identifier>MEX_checksum_bundle</local_identifier>
    <creation_date_time>
      2011-08-23T11:53:24.5749Z
    </creation_date_time>
    <file_size unit="byte">550</file_size>
    <records>10</records>
    <md5_checksum>899fba057920491a08c7d517bd65e717</md5_checksum>
  </File>

  <Checksum_Manifest>
    <local_identifier>MEX_checksum_manifest</local_identifier>
    <offset unit="byte">0</offset>
    <object_length unit="byte">550</object_length>
    <external_standard_id>MD5Deep Version 4.2</external_standard_id>

```

```

        <encoding_type>Character</encoding_type>
        <record_delimiter>carriage_return_line_feed</record_delimiter>
    </Checksum_Manifest>
</File_Area_Checksum_Manifest>

```

10.4 Generating and Populating an XML Label for the “Package”

Using an XML aware editor, the archivist generates the Product_SIP label.

10.5 Identification Area

Populating entries in the Identification_Area of the Product_SIP is identical to that of the Bundle, Collection, and the Basic Product. See Section 3.2 in the Standards Reference [2] for additional information on populating the Identification_Area.

10.6 Reference_List Area

Populating entries in the Reference_List area of the Product_SIP is identical to that of the Bundle, Collection, and the Basic Product. See Section 3.4 in the Standards Reference [2] for additional information.

10.7 Information_Package_Component Area

The following label snippet demonstrates how to populate the Information_Package_Component area of the Product_SIP.

```

<Information_Package_Component>
  <checksum_manifest_checksum>
    899fba057920491a08c7d517bd65e717
  </checksum_manifest_checksum>
  <checksum_type>MD5</checksum_type>
  <transfer_manifest_checksum>
    899fba057920491a08c7d517bd65e717
  </transfer_manifest_checksum>
  <Internal_Reference>
    <lidvid_reference>
      urn:nasa:pds:example.DPH:example:Bundle.Product.MEX::1.0
    </lidvid_reference>
    <reference_type>package_to_bundle</reference_type>
  </Internal_Reference>
  <File_Area_Checksum_Manifest>
    .
    .
    .
  </File_Area_Checksum_Manifest>
  <File_Area_Transfer_Manifest>

```

```

      .
      .
      .
      <File_Area_Transfer_Manifest>
    </Information_Package_Component>
  <Submission_Information_Package>
    <description>
      A brief description of the Pacakge contents goes here.
    </description>
  </Submission_Information_Package>

```

10.8 Delivery of Accumulating Archives

The packaging and manifest constraints are exactly the same for incremental deliveries. However, it is neither required, nor in general desirable, for a provider to redeliver files which have not changed.

Consider a single collection with new files submitted quarterly to the PDS using an external hard drive. Each incremental delivery will have an updated bundle product in the root directory, a sufficient portion of the collection directory structure for each of the files in the delivery to be placed appropriately, and all of the new files. It will also include a transfer manifest for that delivery; however the manifest must be provided to the PDS separately – not on the same external hard drive.

See the PDS Standards Reference [2], Section x.x, for rules regarding Version ID incrementing for incremental deliveries.

10.9 Example Delivery Product Label

For additional information regarding the definitions and cardinality of the attributes and classes used within the definition of a basic product label, consult the PDS4 Data Dictionary.

PART V. LOCAL DICTIONARIES

11.0 LOCAL DATA DICTIONARY

A Data Dictionary serves several purposes. First, the dictionary serves as a reference manual to users of the PDS (and other planetary data systems) to define the attributes and classes that are used to describe planetary data and meta-data. Second, the dictionary serves as a reference for data producers (and others) to aid in the design and understanding of data descriptions. Third, the dictionary has the overall responsibility of ensuring the attributes and classes used in the data descriptions are used in a standard, consistent, predictable manner to the point where each attribute and class can be managed and used as a resource.

Conceptually, a data dictionary defines the attributes and classes which may be used in PDS4 product labels. Practically speaking, it must contain human-readable definitions as well as the syntax and semantic constraints placed on values of the attribute. For classes, it provides the explicit list of attributes constituting the class, and indicates which are required, optional, and/or repeatable. It might also indicate that one or more sub-classes are allowed (or required).

Every attribute and class that is used in any PDS label must first be defined in a data dictionary. Ultimately, all dictionaries will be integrated into the PDS4 Information Model which will “build” the PDS4 Data Dictionary document and the associated Mission and Discipline “dictionary” schemata.

Data dictionaries are categorized into:

- Mission specific
- Discipline specific

Mission specific data dictionaries are those that are comprised of attributes and classes specific to a particular mission or investigation (i.e., the Mars Express mission could create a data dictionary for the sole purpose of defining attributes and classes that describe instrumentation and science data that is particular to the Mars Express mission). Depending upon preference, the mission may elect to have a single data dictionary (that describes both instrumentation and science data) or multiple dictionaries where one dictionary is specific to instrumentation descriptors and another is specific science data descriptors.

Discipline specific data dictionaries are those that are comprised of attributes and classes specific to a particular discipline. For example, the Rings node has attributes / classes that are particular to a large number of Rings products. The Rings node may identify a number of instances where it would be convenient to group Rings descriptors into one or more data dictionaries that are specific to the various types of Ring disciplines.

A local dictionary must reside within a namespace that is unique across all other locally defined dictionaries. In order to avoid collisions among namespaces used in PDS4 labels, the namespace

must either be chosen from a predefined set or created using established formation rules. Refer to the Standards Reference [2], Section 6.1 or confer with your PDS discipline node to determine and/or select an appropriate namespace for each local dictionary for your archive.

11.1 Local Data Dictionaries - The Mission Area

The `Mission_Area`, a subclass of the `Observation_Area`, functionally acts as a container for mission specific classes and attributes of which each are defined in a local data dictionary. The set of locally defined attributes and classes must reside within a namespace that is unique across all other locally defined dictionaries.

```

<!-- ===== -->
<!-- Reference the attributes that were imported from the -->
<!-- local dictionary (using the local namespace (dph) -->
<!-- ===== -->
<Observation_Area>
  .
  .
  .
  <Mission_Area>
    <dph:spacecraft_clock_start_count>
      1246943630
    </dph:spacecraft_clock_start_count>
    <dph:spacecraft_clock_stop_count>
      unkown
    </dph:spacecraft_clock_stop_count>
  </Mission_Area>
  <Discipline_Area>
  </Discipline_Area>
</Observation_Area>

```

11.2 Local Data Dictionaries - The Discipline Area

The `Discipline_Area`, a subclass of the `Observation_Area`, functionally acts as a container for discipline specific classes and attributes of which each are defined in a local data dictionary. The set of locally defined attributes and classes must reside within a 'node' namespace that is unique across all other locally defined dictionaries.

```

<!-- ===== -->
<!-- Reference the attributes that were imported from the -->
<!-- local dictionary (using the local namespace (dph) -->
<!-- ===== -->
<Observation_Area>
  .
  .
  .
  <Mission_Area>

```

```
</Mission_Area>
<Discipline_Area>
  <img:application_process_id>
    1246943630
  </img:application_process_id>
  <img:application_process_name>
    unkown
  </img:application_process_name>
</Discipline_Area>
</Observation_Area>
```

11.3 Building and Using Local Data Dictionaries

Local data dictionaries are categorized into:

- Mission specific
- Discipline specific

This section describes the inter-relationships between the data dictionary schemas, the data dictionary label(s), and the dictionary service that creates the local data dictionary schema.

The dictionary service optionally merges the attributes and classes defined in the local data dictionary with the PDS4 Information Model. This will ensure that your locally defined attributes and/or classes will be contained in the next build of the PDS4 Data Dictionary and the next build of the Generic Mission & Discipline schemata.

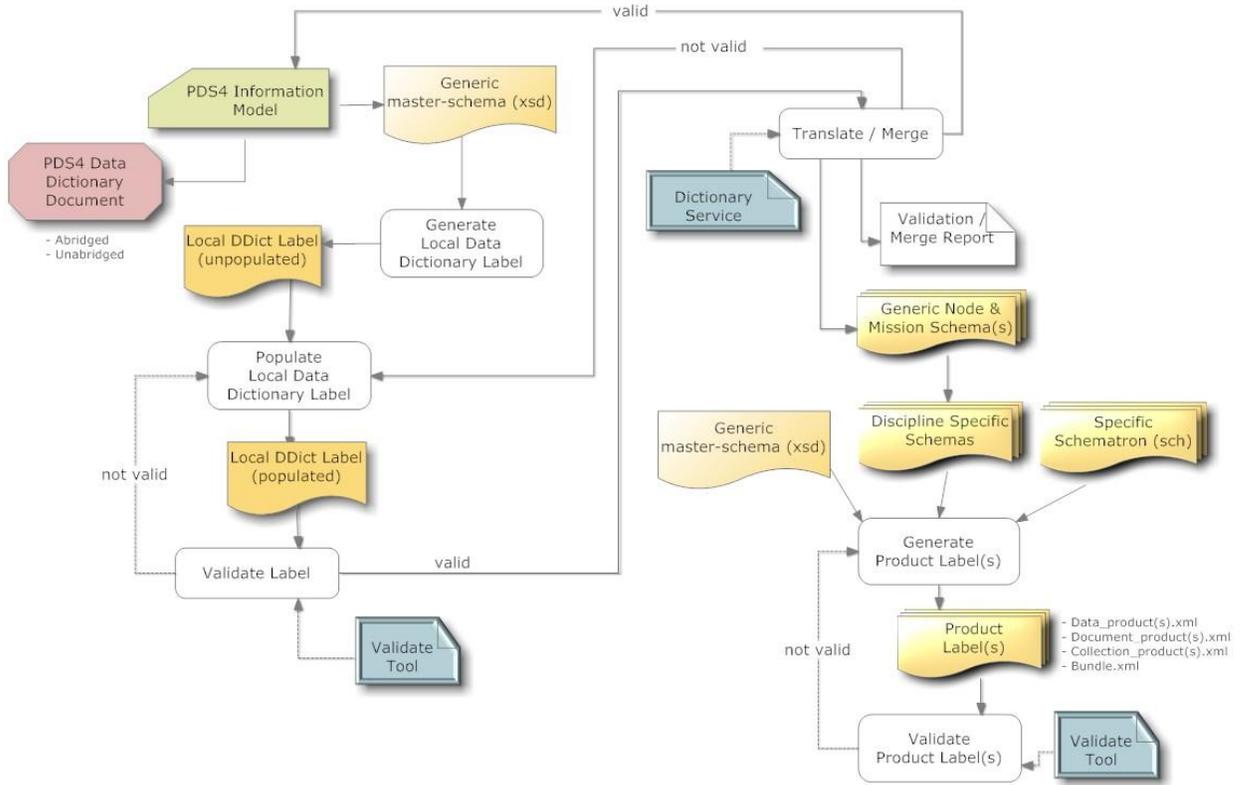

Figure 11-1 Local Data Dictionary Development Flow Diagram

Note that the following examples use Oxygen as the vehicle for demonstrating the local-DD process. In no way does suggest or imply a recommendation or endorsement for using Oxygen over any of the other XML-aware editors.

The steps that follow are a narrative of the major steps to creating a label-template for Ingest_DD. A more detailed description of the generic process of creating a label-template, complete with illustrations, can be found on the PDS Wiki:

<https://odt.jpl.nasa.gov/wiki/display/pdscollaboration/Root%2C+Mission%2C+and+Node+Schemata+to+Label+Template>

Step #1: Download the OPS version of the master-schema:

<http://pds/schema/pds4/dev/generic/ops/>

You will want to copy the master-schema (xsd) file to a local directory / folder.

- Open your favorite browser
- Navigate to the above url
- Select the file of choice to download
- Put your mouse-cursor over the file to be copied
 - right-click and select "Save Link-As" – this will open a dialog box to specify a directory / folder where you want to copy the file

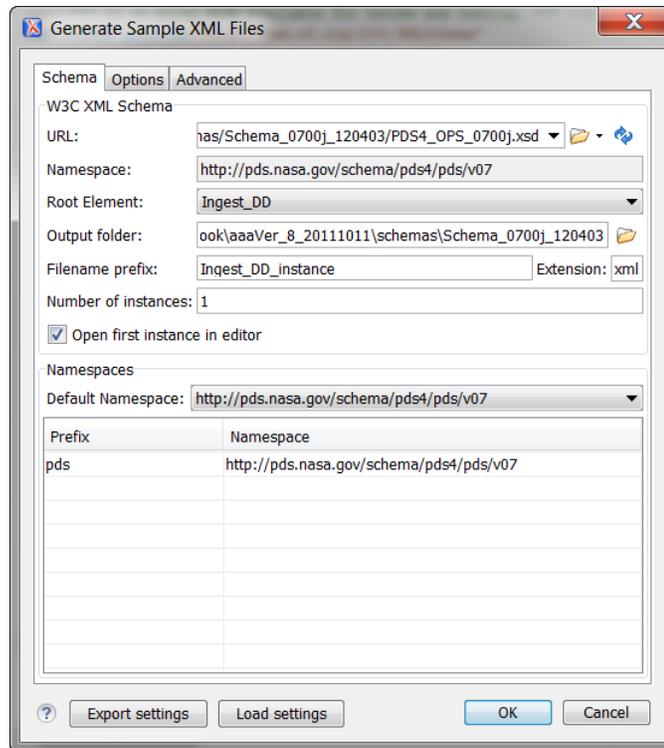

Note that the PDS version of the master-schema does not contain the imbedded reference to the class that we will want to use. Only the OPS version of the master-schema contains an embedded reference to the Ingest_DD class.

Step #2: Using the XML-aware editor of your choice, open the master-schema (xsd) file. Locate the Ingest_DD class. This is the class from which we will generate the label-template.

Step #3: Most XML-aware editors provide a capability to generate a label-template from a schema. In our case, you will want to generate a label-template from the reference to the Ingest_DD class.

In Oxygen:

- select: Tools / Generate Sample XML Files.

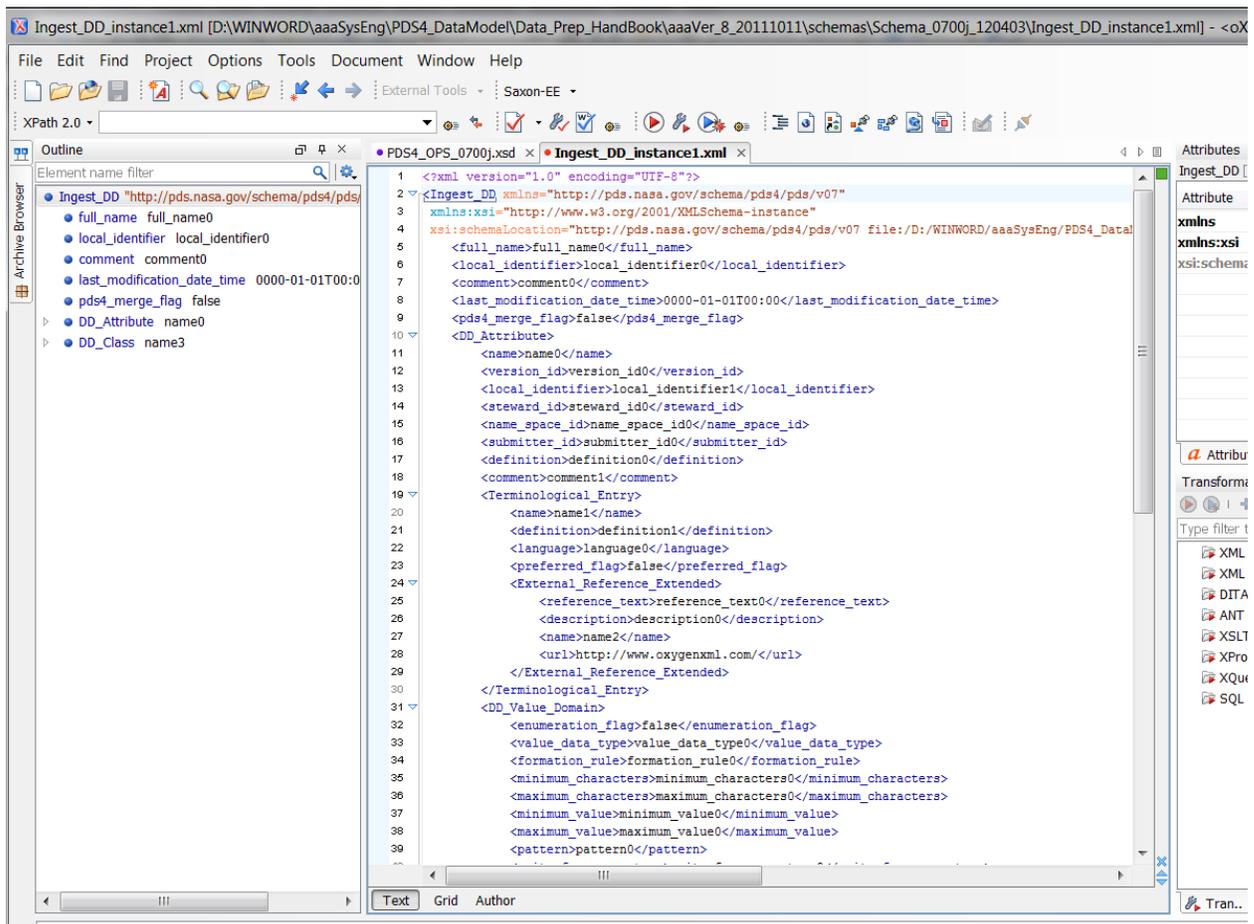

Notice that the "Schema" tab is active. This tab is used to specify the XSD from which the label template will be generated.

- In URL, you will want to specify the local copy of the master-schema file
- In Namespace, the value should be auto-populated with the value specified in the master-schema. The value should be fairly close to the value displayed above.
- In Root Element, you will want to use the drop-down to select the product for which you want to create a label template – Ingest_DD.
- In Output folder, you will want to specify the directory / folder where you want the label template to reside (when created).
- In Filename prefix, you will want to specify the name of the label template.
- In Number of instances, you will most likely want a single instance of the label template to be created. Note that based on the number of instances specified, the value specified in "Filename prefix" will be used as a template for generating multiple instances.
- In Open first instance in editor, you will most likely want to check the box so that the label template will be displayed in Oxygen (when created).
- In Default Namespace, the value should be auto-populated with the value specified in the masterSchema. The value should be fairly close to the value displayed above.
- In Prefix and Namespace, the values should be auto-populated and should be fairly close to the values displayed above.

Once you have verified the above values, select the "Options" tab (at the top of the dialog box).

- In Generate optional elements, you will most likely want to check the box so all optional elements are generated in the label template.
- In Generate optional attributes, you will most likely want to check the box so all optional attributes are generated in the label template.
- In Values of elements and attributes, you will most likely want to select "Default" as the option.
- In Preferred number of repetitions, you will most likely want to specify "1" so that a single instance of all elements and attributes will be generated in the label template.
- In Maximum recursivity level, you will most likely want to specify "1" as the maximum allowed depth in case of recursivity.
- In Choice strategy, you will most likely want to specify "Random" values over "First" value in series.

Once, you verified the above values, click on the "OK" button. This will generate the label template.

From the above step, you should have successfully created a label-template for the Ingest_DD product. With the label-template visible, ensure that in the top right, you can see a little green

box. If the box is red (or not green), the label-template (xml document) is not valid. As the sample label was generated by the XML editor, there shouldn't be any errors. Contact your PDS rep to resolve any discrepancies.

The label-template when populated will become the data-dictionary label.

Step #4: Examine the as-yet-unedited data dictionary label in your favorite XML-aware editor. You are now ready to begin populating the data dictionary label with the metadata associated with each attribute and class that is to be defined in the local data dictionary.

As you populate the dictionary label, ensure that the XML is fully formed (i.e., the XML editor will validate the XML and will have an indicator (which is usually a green or red box) that indicates if errors are present in the XML). Or, you can use the PDS4 Validation Tool to further validate the contents of the XML label.

Step #5: At this point, you should have a fully formed (populated) compliant XML data dictionary label. A decision point has been reached whereby the contents of the locally defined data dictionary may be “merged” with the PDS4 Data Dictionary (via ingestion into the PDS4 Information Model).

To “merge” the locally defined data dictionary with the PDS4 Data Dictionary, set the “pds4_merge_flag” to “true”. If you choose not to “merge”, then set the “pds4_merge_flag” to “false”. Save all changes to the data dictionary label file.

Step #6: In the future, you will eventually access the online Data Dictionary Service, “point” the service to your data dictionary label, and press “go”. The online Data Dictionary Service is under development.

So, the workaround is to email the data dictionary label file to the SE node for processing. The SE data engineer will process your file and create a local instance of the “Node & Mission” schemata (XSD) and a report describing any anomalies encountered while translating / merging.

If you have elected to “merge” the locally defined data dictionary with the PDS4 Data Dictionary, the “service” will additionally validate the contents to ensure a compliant “merge” of the elements and classes is possible (e.g., no duplication of element / class names within the same Registration Authority, etc.). If the SE data engineer doesn't detect any anomalies, then the data engineer will “register” the contents of your data dictionary label with the PDS4 Information Model. This will ensure that your locally defined attributes and/or classes will be contained in the next build of the PDS4 Data Dictionary.

The end result is that you will have online access to the node and mission schemas (xsd).

Step #7: Now that you have a valid local instance of the node and mission schemas (xsd), you can incorporate these dictionaries into your data product pipeline. This is done through an XML include reference in your specific product schema. So, the next step is to “link” the set of discipline and mission schemas (that are to be referenced) into the product schema.

There are four types of references:

- A reference to a schema that is in the same directory as the label-template
- A reference to a schema that is locally-cached / defined
- A reference to a schema that is online accessible
- A reference to a schema using an XML-catalog

In all of the examples that follow, these equivalences are made:

- a. the “pds” namespace to: ["http://pds.nasa.gov/pds4/pds/v08"](http://pds.nasa.gov/pds4/pds/v08)
- b. the “phxmd” namespace to: ["http://pds.nasa.gov/schema/pds4/phxmd/v01"](http://pds.nasa.gov/schema/pds4/phxmd/v01)
- c. the “phxmd” schema file: “phxmd.xsd”

1. Here is an example of a reference where the schema and the label are in the same directory.

```
<Product_Observational xmlns="http://pds.nasa.gov/pds4/pds/v08"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v08"
  xmlns:phxmd="http://pds.nasa.gov/schema/pds4/phxmd/v01"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/phxmd/v01 file:/phxmd.xsd">
```

2. Here is an example of a reference where the schema is locally defined.

```
<Product_Observational xmlns="http://pds.nasa.gov/pds4/pds/v08"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v08"
  xmlns:phxmd="http://pds.nasa.gov/schema/pds4/phxmd/v01"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/phxmd/v01
  file:/D:/schemas/phxmd.xsd">
```

3. Here is an example of a reference where the schema is online accessible.

```
<Product_Observational xmlns="http://pds.nasa.gov/pds4/pds/v08"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v08"
  xmlns:phxmd="http://pds.nasa.gov/schema/pds4/phxmd/v01"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/phxmd/v01
  http://pds.nasa.gov/schemas/phxmd.xsd">
```

4. Here is an example of a reference where the schema is referenced using an XML-catalog. For more information on using XML-catalogs, consult the appendix on XML Catalog references.

```
<Product_Observational xmlns="http://pds.nasa.gov/pds4/pds/v08"
  xmlns:pds="http://pds.nasa.gov/pds4/pds/v08"
  xmlns:phxmd="http://pds.nasa.gov/schema/pds4/phxmd/v01"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pds.nasa.gov/schema/pds4/phxmd/v01 junk.xsd">
```

Step #8: Now that you have all of the pieces in place, you can incorporate all of these files into your data product pipeline that will pump out gazillions of PDS compliant labels --- don't forget to validate, and then validate again, and again, and again...

11.4 Ingest_DD – Attribute Definitions

For additional information regarding the definitions and cardinality of the attributes and classes used within Ingest_DD, consult the PDS4 Data Dictionary.

11.5 Example Ingest_DD Product Label

For additional information regarding the definitions and cardinality of the attributes and classes used within the definition of a Ingest_DD product label, consult the PDS4 Data Dictionary.

An unpopulated sample Ingest_DD.xml template is available [here](#) and a completed Ingest_DD for the Imaging Telemetry_Parameters class is available [here](#).

PART V. VALIDATE THE ARCHIVE

12.0 VALIDATION

This section describes the process of validating the object-oriented design and the inherent relationships of and between the generic schema, the specific node and mission schema, schematron asserts, and the resulting child XML document,

Figure 12-1 illustrates the process by which users ensure the resulting XML documents are compliant to the parent schemas. The validation process guarantees the object-oriented design of the parent-child relationships are preserved throughout the design and implementation stages of preparing XML documents; specifically that:

- The PDS4 product labels validate/are valid against all of the following:
 - a. the generic master-schema
 - b. the specific node and mission schema; if provided
 - c. schematron file(s); if provided.

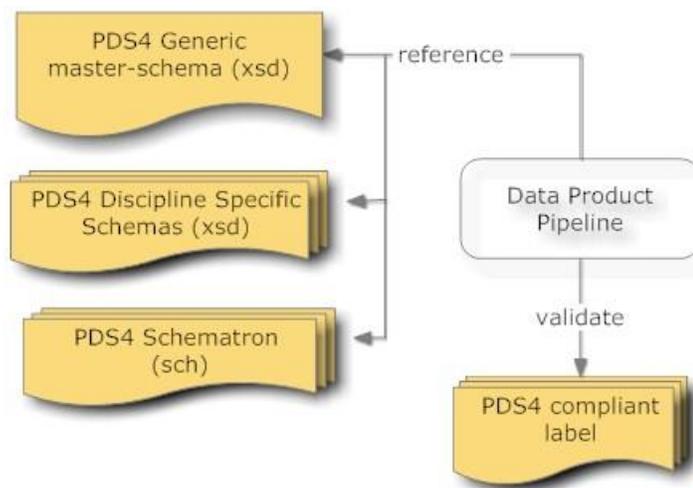

Figure 12-1. Diagram of the Validation of a Product Label

Your Data Product Pipeline will need to incorporate a mechanism by which the pipeline can validate the resulting PDS4 product labels against the noted schema and schematron files.

12.1 PDS Validation Tool

PDS provides a validate software tool which can be found here:

<http://pds.nasa.gov/pds4/software/validate/>

PART VI. SAMPLES, EXAMPLES, OTHER TUTORIALS

13.0 EXAMPLE PDS4 PRODUCTS

A PDS4 tutorial would not be complete without providing a set of PDS4 products that were generated from example PDS3 products.

There are two different sets of examples:

- The first is a set of example products. This includes a representative set of products that would exist within an archive (e.g., character table, binary table, document, etc.).
- The second set is a complete archive. This includes all products that would comprise a complete PDS4 archive (e.g., bundle, collections, collection inventories, readme, errata, and basic products). The archive is presented in a directory structure required of an archive.

This material was originally archived under PDS and is representative of a PDS3 dataset migrated to become a PDS4 “example” archive. Consequently, the products within the “example” archive use “identifiers” that identify the products as “example.DPH” products (i.e., the “identifiers” are not representative of what an actual science archive would use).

This is intentional and allows these products to be registered with the PDS registry service and searchable as “example products” and “example archive”.

13.1 PDS4 Product Examples

The set of PDS4 product examples can be found at:

http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/

Within this set of examples, there is an example of the following product types:

1. ARRAY_2D_IMAGE extension of the PDS4 Array_Base, (i.e., Homogeneous N-dimensional array of Scalars) class where a contiguous stream of BINARY data, assembled as a two dimensional data structure, maps the "items" contained in a ARRAY_2D_IMAGE file.

2. `TABLE_CHARACTER` extension of the PDS4 `Table_Base` (i.e., Heterogeneous repeating record of Scalars) class where a contiguous stream of ASCII characters, assembled as fixed-width fields, maps the "items" contained in a `TABLE_CHARACTER` file.
3. `TABLE_CHARACTER_GROUPED` extension of the PDS4 `Table_Base` (i.e., Heterogeneous repeating record of Scalars) class where a contiguous stream of ASCII characters, assembled as sets of repeating fixed-width fields, maps the "items" contained in a `TABLE_CHARACTER_GROUPED` file.
4. `TABLE_BINARY` extension of the PDS4 `Table_Base` (i.e., Heterogeneous repeating record of Scalars) class where a contiguous stream of BINARY data, assembled as fixed-width fields, maps the "items" contained in a `TABLE_BINARY` file.
5. `TABLE_BINARY_PACKED` extension of the PDS4 `Table_Base` (i.e., Heterogeneous repeating record of Scalars) class where a contiguous stream of BINARY data, assembled as fixed-width fields, maps "Packed_Data_Fields" and "Field_Bit" classes contained in a `TABLE_BINARY` file.
6. `DELIMITED_TABLE` class where a contiguous stream of ASCII characters, combined with a `field_delimiter` and `record_delimiter` scheme, maps the "items" contained in a CSV "like" file.
7. `DOCUMENT` class where one or more instantiations of a document (e.g., ascii text, pdf, html), as identified as a set, comprise a logically complete "copy" of the referenced document product.
8. `HEADER` and `TABLE_CHARACTER` classes illustrating how combined digital objects can co-exist in a single data product file.

The files that comprise the PDS4 example products can be found at:

- PDS4 migrated data_set files (directory listing):

http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_example_products/

A zip file of the PDS4 migrated data can be downloaded from:

http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/zip_ExampleProducts.zip

13.2 PDS4 Example Archive

This set of PDS4 examples were derived from a PDS3 PPI data_set:

```
DATA_SET_ID = "VG2-J-PLS-5-SUMM-ELE-MOM-96.0SEC-V1.0"
```

Both the original PDS3 data_set files and the equivalent PDS4 product files are presented for the purposes of illustrating (comparatively) how a PDS3 data_set can be migrated to PDS4.

13.2.1 PDS3 Data_set Files

The directory structure of the original PDS3 PPI data_set consisted of the following:

- aareadme.txt
- checksums.txt
- errata.txt
- \browse
- \catalog
- \data
- \documents
- \documents\mission
- \documents\pls
- \documents\symbols

The files that comprise the original PDS3 PPI data_set can be found at:

- PDS3 PPI data_set files (directory listing):

http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_example_PDS3_VG2PLS/

A zip file of the PDS3 VG2PLS data_set can be downloaded from:

http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_example_PDS3_VG2PLS/VG2PLS.zip

13.2.2 PDS4 Product Files

The PDS4 archive structure, as migrated from the above PDS3 files, consists of the following:

- Product_Bundle.xml
- README.TXT
- \browse
- \context
- \data
- \document

- \schemas
- \local_dictionaries

The following PDS3 files have been relocated to the “document” directory:

- checksums.txt
- errata.txt

The files that comprise the PDS4 migrated data_set can be found at:

- PDS4 migrated data_set files (directory listing):

http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_example_archive_VG2PLS/

A zip file of the PDS4 migrated data can be downloaded from:

[http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_example_archive_VG2PLS/
zip_VG2PLS_archive.zip](http://pds.jpl.nasa.gov/repository/pds4/examples/dph_examples_3a/dph_example_archive_VG2PLS/zip_VG2PLS_archive.zip)

APPENDIX A ACRONYMS

The following acronyms pertain to this document:

ADM	Architecture Development Method
API	Application Programming Interface
COTS	Commercial Off-The-Shelf
EN	Engineering Node (PDS)
ESDIS	Earth Science Data and Information System
FTP	File Transfer Protocol
IEEE	Institute of Electrical and Electronics Engineers
IPDA	International Planetary Data Alliance
IT	Information Technology
JPL	Jet Propulsion Laboratory
NASA	National Aeronautics and Space Administration
NSSDC	National Space Science Data Center
PDS	Planetary Data System
RM-ODP	Reference Model of Open Distributed Processing
RSS	Really Simple Syndication
SDSC	San Diego Supercomputing Center
SOA	Service-Oriented Architecture
TB	Terabyte
TOGAF	The Open Group Architecture Framework
XML	eXtensible Markup Language

APPENDIX B XML REFERENCES

[TBD]

APPENDIX C SCHEMATRON REFERENCES

In [markup languages](#), **Schematron** is a rule-based [validation](#) language for making assertions about the presence or absence of patterns in [XML](#) trees. It is a structural schema language expressed in XML using a small number of elements and [XPath](#).

Schematron is capable of expressing constraints in ways that other XML schema languages like [XML Schema](#) and [DTD](#) cannot. For example, it can require that the content of an element be controlled by one of its siblings. Or it can request or require that the root element, regardless of what element that is, must have specific attributes. Schematron can also specify required relationships between multiple XML files.

Constraints and content rules may be associated with "plain-English" validation error messages, allowing translation of numeric Schematron error codes into meaningful user error messages.

An example of a schematron “rule” follows:

```
<sch:pattern>
  <sch:rule context="pds:Identification_Area">
    <!-- ===== -->
    <!-- Test: ensure 'information_model_version' value -->
    <!-- matches expected-value -->
    <!-- ===== -->
    <sch:assert test="pds:information_model_version='0.3.0.0.a'">
      Identification_Area.information_model_version: does NOT specify
      the current version.
    </sch:assert>
  </sch:rule>
</sch:pattern>
```

The above rule ensures the value for the `information_model_version` attribute in the `Identification_Area` exactly matches ‘0.3.0.0.a’:

A primer to schematron is available on the PDS Wiki:

<https://oodt.jpl.nasa.gov/wiki/display/pdscollaboration/Validation+of+PDS4+XML+Labels>

- A good set of introductory tutorials are available here. There is no need to run through all of the tutorials. But Two Types of XML Validation, Usage and Features, and Overview will set the stage of what Schematron is :
 - <http://www.xfront.com/schematron/index.html>
- Great set of starter examples and how to:
 - <http://zvon.org/xxl/SchematronTutorial/General/toc.html>
- A walk through of schematron:

- <http://www.ibm.com/developerworks/xml/tutorials/x-schematron/>

APPENDIX D XML CATALOG REFERENCES

[XML](#) documents typically refer to external entities, for example schemas for the Document Type Definition. These external relationships are expressed using URIs, typically as URLs.

However, if they are absolute URLs, they only work when your network can reach them. Relying on remote resources makes XML processing susceptible to both planned and unplanned network downtime.

Conversely, if they are relative URLs, they're only useful in the context where they were initially created. For example, the URL "../xml/dtd/docbookx.xml" will usually only be useful in very limited circumstances.

One way to avoid these problems is to use an entity resolver or a URI Resolver. A resolver can examine the URIs of the resources being requested and determine how best to satisfy those requests. The XML catalog is a document describing a mapping between external entity references and locally-cached equivalents.

The following is an example of a XML catalog that resolves the locations of schemas as the schemas follow a somewhat natural development cycle of: DEV, ARCHIVE, and ONLINE.

```
<?xml version="1.0" encoding="UTF-8"?>
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
  <!-- ===== -->
  <!-- 1st reference is to DEV instance -->
  <!-- ===== -->
  <group xml:base="file:/D:/DEV/schemas/">
    <uri name="http://pds.nasa.gov/pds4/pds/v03" uri="PDS4_PDS_0300a.xsd"/>
    <uri name="http://pds.nasa.gov/schema/pds4/phxmd/v01" uri="PHXMD_0300a.xsd"/>
    <system systemId="PDS4_PDS_0300a.xsd" uri="PDS4_PDS_0300a.xsd"/>
  </group>

  <!-- ===== -->
  <!-- 2nd reference is to ARCHIVE instance -->
  <!-- ===== -->
  <group xml:base="file:/D:/ARCHIVE/schemas/">
    <uri name="http://pds.nasa.gov/pds4/pds/v03" uri="PDS4_PDS_0300a.xsd"/>
    <uri name="http://pds.nasa.gov/schema/pds4/phxmd/v01" uri="PHXMD_0300a.xsd"/>
    <system systemId="PDS4_PDS_0300a.xsd" uri="PDS4_PDS_0300a.xsd"/>
  </group>

  <!-- ===== -->
  <!-- 3rd reference is to ONLINE instance -->
  <!-- ===== -->
  <system systemId="http://pds.nasa.gov/schema/pds4/phxmd/v01"
uri="http://pds.jpl.nasa.gov/schemas/PHXMD_0300a.xsd"/>
  <uri name="http://pds.nasa.gov/schema/pds4/phxmd/v01"
uri="http://pds.jpl.nasa.gov/schemas/PHXMD_0300a.xsd"/>
</catalog>
```

Once the XML catalog has been created, the catalog file will need to be “registered” with the XML-aware editor that you are using. Once registered, you will also need to validate that the XML-catalog is being referenced by your XML product labels.

- A primer to XML Catalogs is available on the PDS Wiki:

<https://oodt.jpl.nasa.gov/wiki/display/pdscollaboration/XML+Catalogs>

The primer will take you through the following steps:

1. *Example Schema / XML Labels)*
2. *XML Catalog Solution, Part 1: schemaLocation Changes*
3. *XML Catalog Solution, Part 2: Creating an XML Catalog File*
4. *XML Catalog Solution, Part 3: Configuring the XML Catalog*
5. *XML Catalog Solution, Part 4: Validating the XML document using the XML Catalog*
6. *XML Catalog Solution, Part 5: Using XML Catalog to make schemas Portable*

APPENDIX E STEPS TO CREATE A LABEL TEMPLATE

This appendix illustrates the steps that can be used to create a label-template from the master-schema (xsd).

Steps:

1. Download a copy of the current masterSchema (xsd)
2. Open the masterSchema in xml-aware editor (XAE)
3. Customize the settings
4. Create label template (xml)
5. Ensure label template is valid

Step 1: Download a copy of the current masterSchema (xsd)

The current version of the PDS4 masterSchema (xsd) can always be found here:

<http://pds.nasa.gov/schema/pds4/current/generic/common/>

The two files of interest are:

- The current schematron file: PDS4_PDS_XXX.sch
- The current masterSchema file: PDS4_PDS_XXX.xsd

You will want to copy both of the above files to a local directory / folder.

- Open your favorite browser
- Navigate to the above url
- Select the file of choice to download
- Put your mouse-cursor over the file to be copied
 - right-click and select "Save Link-As" – this will open a dialog box to specify a directory / folder where you want to copy the file
 - repeat for the 2nd file

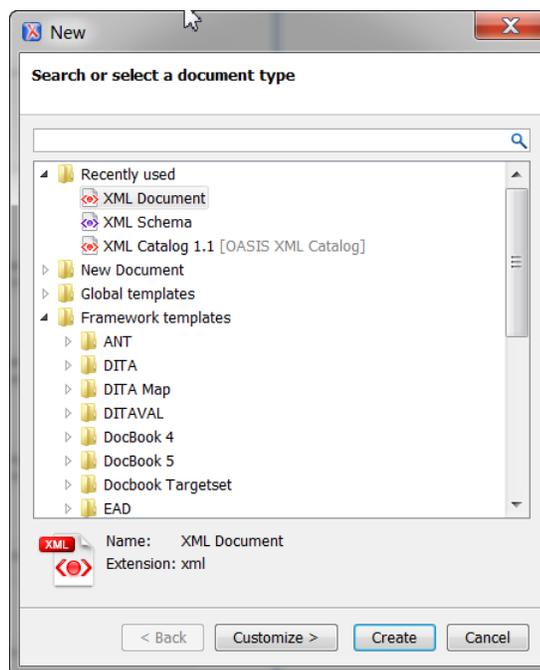

Step 2: Open the masterSchema in XML-aware Editor

From Step 1, you should have a local copy of the masterSchema (xsd) and the schematron (sch) files.

Using your favorite xml-aware editor (XAE), open the masterSchema (xsd) file.

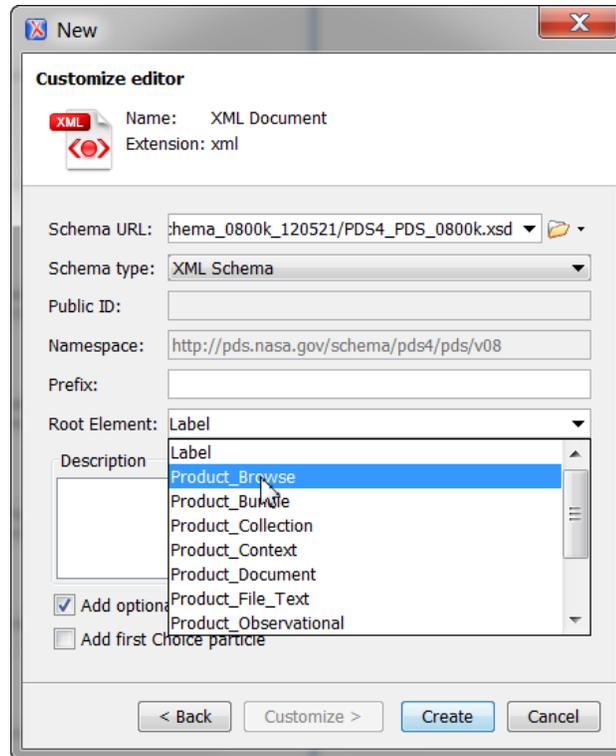

The next step is to identify the product for which you want to create a label template. The XAE The next step is to the XAE to create a new document. You will want to create a new “XML Document”.

Step 3: Customize the Settings

Before you create the document you will need to “customize” some of the information that will be needed to create the label-template (xml) document that will suit your purpose.

The masterSchema includes references to a number of "products" each of which represents a distinct set of product classes. Product classes are, by definition, the highest level classification of the product into a category like "observational product" or "document":

1. We need to populate the ‘Schema URL’ with the full path to the masterSchema. Either drag-and-drop the masterSchema (xsd) or type the path.
2. For ‘Schema type’, select ‘XML Schema’ as the type of schema being referenced.
3. The ‘Namespace’ value should be pre-populated with the namespace identified in the masterSchema.
4. For ‘Root Element’ select the type of product that you want to create (e.g., Product_Browse, Product_Observational, etc).
5. You will most likely want optional content to be added when the label-template is created, so select ‘Add optional content’.

Step 4: Create the label-template (xml) document

You are now ready to have the XAE create the label-template:

1. Click on ‘Create’.
2. The label-template will auto-display in the XAE.
3. You will probably want to ‘Save’ the file locally.

Step 5: Ensure the label-template is valid (or not)

From Step 4, you should have a local copy of the label-template (xml) document. The XAE provides a simple visual indication of whether or not the XML file is valid.

The label-template that we generated from Step 4 will most likely not be valid as there are no values specified within the xml tags. Once a full set of values has been specified, the label-template should become valid:

1. With the label-template visible in the XAE, ensure that in the top right, you can see a little green box. If the box is red (or not green), then label-template (xml document) is not valid.
